I know of but two instances, though there may be more, in which this operation has been actually performed. They are recorded in the 30th and 31st volumes of the *Medico-Chirurgical Transactions*, the one by Dr. Golding Bird, and Mr. Hilton, jointly; the other by Mr. Druitt. Though the operations failed to save the lives of the patients, the narratives of these two cases plainly show how life may, peradventure, be saved under similar circumstances. In both cases the strangulated portion of intestine was found in the expected place—and was liberated. The sagacity which comprehended the nature of the mischance, the skill and courage which planned and attempted its redress, were sufficiently vindicated; but the patients ultimately sank: Mr. Hilton's from exhaustion apparently; Mr. Druitt's from rupture of an ulcerated portion of intestine not far from the place of the obstruction. Had the operations been performed earlier, they might perhaps have been successful: but consent to their performance was not obtained until the strangulation had already existed for fifteen days in the first case, for fourteen days in the second.

The cases best adapted to this bold measure—could we but discriminate them beforehand—would obviously be those of internal strangulated hernia, or of twisted bowel, occurring in persons previously and otherwise in good health.

A clue towards discovering the situation of the impediment may sometimes be obtained from the circumstances of the particular case. If large enemata find a ready passage, the obstacle can scarcely be lower than the valve of the cæcum. If urine be copiously secreted, it cannot be very high up in the small intestines. Dr. Barlow was the first to draw attention to this guiding symptom, and to explain it. If fluids, after being swallowed into the stomach, are unable to find their way into, or far into, the intestines, so as to allow of their passage by absorption or by imbibition, into the capillaries of the portal system, those fluids cannot reach the emulgent arteries, and very little urine will be secreted. The fluids swallowed will, in fact, be soon rejected by vomiting: so that early and frequent sickness is a presumptive sign that the impediment lies in the upper part of the intestinal canal. When it is situated in the large bowel, sickness is late, in general, to come on, unless it be excited by drugs, or by accumulating food. The same accomplished physician points out the lesson to be

learned from the degree of fulness of the abdomen. In the extreme case of obstruction of the duodenum, it is flat, or even sunken; in the other extreme, of the rectum, of the sigmoid flexure, it is distended and resonant; and intermediate obstacles give intermediate degrees of fulness. Sometimes the sensations of the patient guide us to the place: he feels that food and drink, or flatus, pass in the one direction, and injections in the other, as far as a certain point, but never beyond it. Occasionally, pain or tenderness in a particular spot, or a palpable tumour, may indicate the site of the obstruction.

It remains that I should say something more respecting *colic*; which may exist independently of enteritis, and of mechanical occlusion of the bowel: although the three are very often combined and intermixed in the course of the same disease.

In colic there is pain in the abdomen, constipation of the bowels, vomiting often: and these are symptoms which occur also in enteritis. The pain is a twisting or wringing pain generally, round the navel: and such is the character of the exacerbations of pain experienced when the bowels are inflamed. These are the points of *resemblance* between the two maladies: and it is of much importance, as I told you before, to observe their *differences*; and to note the marks by which the one may be distinguished from the other. It is, then, an essential difference that enteritis is attended with fever, and with tenderness of the belly. The pain is increased by all kinds and every degree of pressure; and the patient, fixed in the supine position, breathes with the intercostal muscles only, and carefully avoids any movement which would call the abdominal muscles into action, and so compress the inflamed bowels. In colic, on the other hand, the circulation is tranquil; there is no fever; and the pain is even mitigated by pressure. The patient will lie on his belly for ease; nay, he will press it with the whole weight of his body across the back of a chair, and obtain comfort by that expedient. During the paroxysms the pain is often most violent; what the old writers call *dolor atrox*—atrocious pain: but there are intervals of complete ease. Even when the pain is worst, the patient tosses and shifts from one posture to another in search of relief; and he does not wear that anxious and apprehensive aspect which we see in those who are labouring under enteritis. The pain arises, I imagine, from the distension of the bowel, here and there, by gas; or, it may be, from spasm; or from both these states at once. At any rate, it is often associated with audible flatulence, and with evident outward spasm. The abdomen is hard, and drawn spasmodically inwards towards the vertebral column; and its muscles are partially and strongly contracted, gathered up into lumps and knots. None of these circumstances belong to enteritis.

However, there is good reason for believing that, even in mere colic, the pain may sometimes be augmented by pressure. When a portion of the gut has become rapidly distended, considerable uneasiness may result from its forcible compression, although, as Dr. Abercrombie states, the kind of pain can generally, by attention, be distinguished from the sensitive tenderness of an inflamed peritoneum. Luckily, if such pain on pressure should lead us to mistake a case of pure colic for a case of enteritis, the error is on the safe side: and we must always bear in mind the tendency remarked in colic, when the complaint is neglected or badly treated, to run into actual inflammation. In fact, as any obstacle to the passage of the alimentary matters through the bowels may give rise to colic, colic is sometimes merely the first step towards acute inflammation arising out of a continuance of the obstruction. And having told you that colic may be thus produced, I have at once introduced you to a large class of its causes, which have already been spoken of in the present lecture as frequent causes of inflammation also.

But colic, like inflammation of the bowels, sometimes arises without any apparent or detectible obstruction, of a mechanical kind, to the free transit of the contents of the alimentary tube. And there is one particular form of colic that requires a separate notice. The colica *Pictorum*—so called from its great frequency, heretofore, among the Pictones, or inhabitants of Poitou—is produced by the slow introduction of the poison of lead into the body.

Now the colic which has this origin is not to be distinguished, in its ordinary symptoms, from any other kind of colic. But the abdominal pain is usually, in such cases, a part only of more general disease. It has received, in different places, a variety of names. Colica Pictorum; the painter's colic; the Devonshire colic; the

bellain of Derbyshire; the dry belly-ache of the West Indies. In all cases it acknowledges the same cause—the gradual entrance of lead into the system.

In this country we see the disease more often in painters than in any other persons. They use, as you know, white lead in the preparation of their colours; and they are perfectly familiar with this terrible colic. We see it also among all workmen whose occupations bring them habitually into contact with preparations of lead. No doubt there are very great differences in the susceptibility of this effect of the poison of lead. Persons have been known to suffer colica Pictonum, in consequence of their sleeping for a night or two in a recently-painted room. On the other hand, I have myself seen a patient who became affected with the disease for the first time, after working with white lead for nineteen years. Generally the first attacks of colic are well recovered from. The obstinate constipation of the bowels is at length overcome; the patient obtains ease; and forthwith recurs to his previous habits; and after a period, which varies in different individuals, he is again laid up with the colic. Even the primary attacks are usually attended with pains in the head and in the limbs; sometimes with cramps; sometimes even with epilepsy and coma. At length, in one of these attacks of colic, or after one of them, when the violence of the pain, and the costiveness, have yielded to treatment, the patient finds that he has lost the full power of using one or both of his hands. The wrists, as the patients express it, *drop*. You see at once what is the matter, by the characteristic state of the arms and hands. The extensor muscles of the hands and fingers, and the supinator muscles of the fore-arms, are palsied: so that when the arms are stretched out, the hands hang dangling down by their own weight; and the patient is unable, by any effort of his will, to raise them. The palsy is local; it does not proceed from any diseased condition of the nervous centres. The affected muscles waste; and the atrophy is very remarkably seen in the bundle of muscles composing the ball of the thumb. Even from this condition the patients often are capable of complete recovery. But if they persist in following their former calling—or if without knowing it, they continue to be habitually exposed to the exciting cause of the disease—they become miserable cripples, lose their power of sleeping, fall into a state of general cachexia, and sink at length under some visceral disease. The poison accumulates in the body, and saps the power of life. Francis Citois, a native of Poictou, who published an excellent, and one of the earliest, accounts of the disease, in the year 1617, has drawn the following graphic picture of its effects. Its cause was not at that time suspected. Speaking of the wretched sufferers, he says, “*Per vicos, veluti larvæ, aut arte progredientes statuæ, pallidi, squalidi, macilenti, conspiciuntur; manibus ineuvis, et suo pondere pendulis, nec nisi arte ad os et cæteras supernas partes sublatis, et pedibus non suis sed crurum musculis, ad ridiculum ni miserandum incassum compositis, voce clangosâ et streperâ.*”

The course of the disease is usually such as I have just described it. The colic happens first, perhaps several times: and then arrives the palsy. But in a few instances I have known this order reversed. The wrists have dropped, when there had been no preceding colic.

The great cause of this fearful malady was first made out by our distinguished countryman, Sir George Baker. He set on foot an inquiry into the origin of what was called the *Devonshire colic*; so common was it in that county. He found, first, that it occurred chiefly in persons who drank the *cider* manufactured there: and, by degrees, he traced the source of the malady to the admixture of lead with the cider; either designedly, for the purpose of sweetening it; or by the inadvertent employment of lead in the construction of the cider mills and vats. It was under circumstances of the same kind that the colic of Poictou originated. Preparations of lead were used—not fraudulently, but openly and honestly—to prevent the wines of the country from turning sour; the injurious influence of lead upon the human body not having then been ascertained. So also, equally convincing proofs of the adulteration of *rum* by means of lead, giving rise to frequent attacks of dry belly-ache in the West Indies, are given by Dr. John Hunter, in the *Medical Transactions*. I invite your attention to his papers, and to Sir George Baker's on this subject. They afford a capital specimen of medical research and reasoning. Various causes, as you may suppose, had been assigned for this disorder. These are one by one investigated, and set aside; until, by this method of exclusion, the real source of all the mischief

is detected. Sir George Baker's papers contain a great deal of curious and useful information in respect to the various modes in which this poison of lead may find its way, without being suspected, into the animal economy. The subject is one of vast importance in its relation to medical police; but my limits will not allow me to follow it beyond the point where it ceases to be directly connected with the practice of physic.

Colica Pictonum is seldom fatal as colic; or during the persistence of the abdominal symptoms: yet instances enough of death occurring while the colic was present, but from other accidental causes, have now been collected, to enable us to say, that no appearances have been met with in the intestinal canal, calculated to explain the pain or the constipation. Andral relates five cases, in which the body was carefully examined after death preceded by the painter's colic. He found neither inflammation, nor any remaining trace of spasm. The intestines were neither dilated nor contracted, but of their natural texture and appearance. M^{érat}, who has written a good treatise on this form of colic, gives the dissections in four fatal cases: fatal, as I mentioned that they sometimes are, by the supervention of coma. There was no discoverable mark of disease; the alimentary canal was empty, and the large bowels contracted; as they were also found to be in rabbits which had died of lead colic. For animals are susceptible of the disease, and it may be produced in them by the slow impregnation of their bodies with the specific poison. Dogs, cats, and rats, that inhabit houses and manufactories wherein lead is much used or prepared, are known to be attacked both with colic and with palsy. With respect to the contraction of the large intestines in these cases, we must not be too ready to attribute it to spasm; for the bowel, when empty, is apt to be contracted.

When the palsy has been of any continuance, the affected muscles not only shrink and waste, but undergo a structural change, which is obvious to the sight. They become pale, almost white, dry. John Hunter examined the muscles of the hand and arm of a house-painter, who died, while thus paralytic, in St. George's Hospital. He found them of a cream colour and opaque; instead of being of a purplish red, and semi-transparent. And since his time, lead has been detected in the palsied muscles, and in the brain, by chemical analysis. It is doubtless conveyed by the blood, to all parts of the body. Why it fastens solely or chiefly on particular muscles, or particular nerves, nobody knows. The pain it occasions, whether in the abdomen or in the limbs, is generally thought to be neuralgic. It is one of the poisons that do not appear to find a ready exit from the body. Very recently, a most curious symptom, pathognomonic, I believe, of the presence of lead in the system, has been pointed out by Dr. Burton: and now that it has been pointed out, one can hardly understand how it escaped discovery so long. It is a blue or purplish line running along the edges of the gums just where they meet the teeth. Dr. Burton first noticed this six years ago, but wisely refrained from making his observations public until he had had time and opportunity enough to satisfy his mind that he was not mistaken. A paper of his on the subject was read at the Medical and Chirurgical Society last January (1840). I cannot resist the temptation to read to you from my notes the substance of a case which has subsequently occurred to me in the Hospital. Mary Anne Davis, a middle-aged woman, presented herself with dropped wrists. It was an exquisite example of palsy of the extensor muscles of the hands and fingers. She could raise her arms, but her hands hung down like the talons of a bird, or like the fore paws of an erect kangaroo. This began nine weeks before. She complained of pain, beginning under the nails, stretching up the backs of her hands, and reaching sometimes to the elbows. The bottoms of her feet had also been tender: and at night were burning hot.

Seeing the dropped wrists, we thought immediately of the poison of lead. But the patient was a female. We do not often meet with these effects of that poison in women; for obvious reasons. At first we could get no clue to the mode in which lead might have found its way into her system. Her husband was a broker. She had not been living in a newly-painted house: and had (she said) no concern with lead in any way. Lead often creeps in, however, through undetected channels, and I could not help suspecting it here. Mr. Pyper, my clinical assistant, soon elicited another part of her history, which added to our suspicions; namely, that before the palsy occurred, she had had pains in the abdomen, and costive bowels, for five days

together. Nay, she had a recurrence of eolie after her admission. This was a strongly corroborating fact; but what elenched the proof was the discovery of a decided blue rim along the edges of nearly all her gums. This conclusive evidence led to further cross-examination; and at last it came out that some of her sons (she had seven) had occupied their leisure time in the preceeding summer with making bird-cages, and painting them green, in the one room in which she habitually lived. The case was altogether a very neat one.

Mr. Tomes has taken advantage of the opportunities furnished by his office of dentist to the hospital, of inquiring into this remarkable phenomenon; and has come to the conclusion that the colour is produced by some chemical action between the tartar that forms on the teeth, where they meet the gums, and the lead which pervades the system. This woman's teeth, like those of many in her rank of life, were loaded with tartar. In one place was visible a stump level with the gum, and surrounded by a ring of tartar; and *there* was also a corresponding border of blue. In other places there were gaps, where teeth once were: here there was, of course, no tartar; and here there was no blue line on the edge of the gum. The presence of tartar is the thing necessary. The teeth are so, only as affording lodgment for the tartar. When the tartar is thoroughly removed from the neck of a tooth, the blue tinge gradually fades from the corresponding gum, while it persists around the teeth upon which the tartar is suffered to remain. Mr. Tomes extracted "an aching tooth for a lady who had taken two or three doses of acetate of lead, for the suppression of uterine hæmorrhage. Her gums exhibited the characteristic blue line. Nine days after the removal of the tooth, the gums had come together, and the union was marked by a transverse blue line. At the expiration of three weeks the blue line had wholly disappeared."

Some instances have occurred, under Mr. Tomes' observation, of strongly marked blue gum, without any other indication of the presence of lead in the system, and without any evidence of the exposure of the patient to the influence of that metal. In fact, he suspects that other metals may sometimes produce a similar discoloration of the gum. Should this hereafter be proved, the diagnostic value of this test of the operation of lead will be somewhat impaired.

"The colouring material is probably sulphuret of lead, or a similar salt of some other metal. Tartar, being very porous, admits into its substance fluids charged with animal matter, which may there be decomposed, and furnish sulphuretted hydrogen. Supposing a salt of lead to be present, a sulphuret of lead would be formed, which would give the colour in question to the tissue in which the formation took place."

"The saliva itself contains sulpho-cyanic acid, and from this source sulphur might also be furnished."

This discovery of Dr. Burton's is not a mere piece of curiosity, but is likely to be of use in various ways. In the first place, it may settle the nature and cause of many doubtful cases; as it did, indeed, of the one just narrated; and of another which I have met with since. I was sent for to Ventnor to see a lady who was thought to be dying of cerebral disease. She had arrived at that place from a distant part of the country, in a partially insensible condition; and she soon became completely comatose. A week previously she had had a fit of convulsions, followed by double vision, and ocular spectra. The coma had nearly passed away before I saw her. This lady had been ailing for some time. Two things in particular struck Dr. Martin (whom I met in consultation) and myself. She had suffered repeated attacks of abdominal pain and constipation; and the edges of her gums were blue. A faint shade of the same colour extended over the gums a little way below their edges. Further inquiry brought to light the fact that she had been living in a house where all the water used for drinking and for cookery was taken from a certain cistern; and this water, when subjected to chemical tests, was found to be impregnated with lead. Our patient recovered. Again, the poison of lead produces pains which resemble, and no doubt are sometimes mistaken for, the pains of rheumatism; it has other obscure consequences too: and an inspection of the gums may often greatly elucidate such cases. Dr. Burton found that small quantities of lead given as medicine will sometimes produce the phenomenon. In two instances it occurred within two days. One of these patients had taken fifteen grains of the acetate of lead in that time; the other twenty-four grains. A correspondent of his produced the blue rim in twenty-

four hours; viz., by four doses of five grains each, exhibited every six hours. He found too that the line remains distinct after death; even more so than during life. It may afford valuable information therefore to the medical jurist in cases of suspected poisoning with the salts of lead. It is, I say, an *early* consequence of the absorption of lead. It may teach us, as the mercurial affection of the gums teaches us, that the medicine is pervading the system; and admonish us to look out for, and guard against, colic. It may apprise workers in lead that their caution has been insufficient; that the poison has entered; and that they are in peril of belly-aches and palsy. It is a capital diagnostic sign also between colic so arising, and colic from other causes; and between colica Pictonum, and the pain of inflammation of the bowels.

In the year 1832, colic became suddenly epidemic among our troops stationed at Newera Ellia, in Ceylon. More than seven tenths of the whole force were attacked by this complaint, which in seven instances proved fatal. All the sick persons presented the characteristic blue marks. The disorder was traced by Dr. Alexander Smith, to the presence of lead in a sample of coarse sugar, distributed among the soldiers from one particular estate in the island. There was strong reason to suspect that, in the manufacture of this sugar, acetate of lead had been added to the cane-juice instead of lime. But Dr. Smith shows how the carbonate of that metal might easily get mixed, in small quantities, with the sugar, as it was ordinarily prepared there: plates of lead being laid over some parts of the apparatus employed.

Dr. Smith paid especial attention to the "blue-line" on the gums. He believes that it is produced by the gradual introduction of lead into the system, and by lead *only*. When caused by lead administered medicinally, he had seen it exist for weeks without the supervention of colic. It never appeared under the continued use of sulphate of copper, or of mercury. In all other points Dr. Smith's opinions respecting this marking of the gums coincide with those of Mr. Tomes.

In Dr. Hassall's remarkable book on Adulterations, some striking instances are given of lead poisoning, from a source which might easily be overlooked—namely, from the use of *snuff*, falsified by the admixture of the red oxide, or sometimes of the yellow chromate, of lead.

[The symptoms of colica pictonum, or lead colic, are in some respects different from those of ordinary colic. There is usually, at first, a loss of appetite, with some degree, more or less in different cases, of nausea, and very commonly an increased discharge of saliva. The patient's sleep is disturbed, or more frequently, there is an inability to sleep. According to M. Ranque, of Orleans, he exhibits various other symptoms of a disordered condition of the nervous system. The attack of colic usually commences with vomiting; the matter discharged being, at first, whatever has been taken into the stomach, mixed with bile and the gastric secretions, very generally changed from their healthy condition; if the vomiting continue, these latter are alone discharged. Pain of the abdomen is next complained of; it is most severe about the navel, the epigastrium, the hypochondria, the loins, and above the crest of the ileum. The pain, in general, commences at the hypogastric region, or, as a cramp, at the pit of the stomach, and from thence extends, in a short time, over the rest of the abdomen. The pain is at first paroxysmal, with intervals of ease; these intervals being the longest at the commencement of the attack. More commonly there occur remissions rather than intermissions of the pain; and it is remarked, that both the remissions and exacerbations are much longer than those of ordinary colic. As the disease advances the pain is almost constant, but is usually most severe at night. It is not increased by pressure; on the contrary, pressure very generally, but not invariably, affords relief, provided it be not made upon the epigastrium. According to Mérat, patients have been known to bear, with relief to the paroxysms, the weight of two or three persons standing on the belly. The abdomen is almost invariably hard and flat, from a contraction of its muscles; the navel is sometimes drawn in so as almost to approach the spine. In a few instances there exists some fulness of the abdomen, and occasionally it has an irregular, knotty feel. There generally occur, within the first day or two, sometimes within the first few hours of the attack, headache, and a dull, anxious, or depressed expression of the countenance. To these symptoms are soon added, pains of the limbs, especially of the inside of the thighs, calves of the legs, ankles, and soles of the feet; these pains are worst at night; they

are often accompanied with cramps, and according to Tanquerel, are relieved by pressure. The disease is seldom attended with febrile excitement. The skin is of a dull, dirty, cadaverous appearance; it is frequently hot, and almost invariably bedewed with irregular, clammy, and often cold, perspiration. The pulse, according to MM. Ranque and Mérat, is rarely accelerated, but often below 60° in a minute; others, however, notice a considerable acceleration of the pulse, which we have remarked in many cases, the pulse being at the same time hard, and communicating to the finger a peculiar thrill. Obstinate constipation of the bowels is an almost invariable symptom; although it does not always occur at the very commencement of the attack. In a few instances, it is said that the attack has been attended with diarrhoea; such an occurrence, however, we have never observed; on the contrary, in all the cases that have fallen under our notice, either no discharge has taken place from the bowels, or a scanty stool has occurred composed of a few lumps of dry, hardened feces, passed with much straining and pain. The urine, though generally natural in appearance, is often diminished in quantity.

From an attack of colica Pictonum, particularly a first attack, the patient may, under a judicious and timely treatment, recover perfectly; and with a careful avoidance of its exciting causes, and of the poison of lead, he may remain ever after free from a recurrence of the disease. When the disease, however, is neglected, or badly managed, or the patient is constantly or repeatedly exposed to the influence of lead, he becomes affected either with a peculiar form of partial palsy, which is well described by Dr. Watson in the text; or, instead of this gradual loss of voluntary motion in the muscles of the extremities, there may occur another set of symptoms, which very generally terminate speedily in death. The patient after a few days becomes affected with giddiness, great debility, torpor, and sometimes delirium: as the torpor advances, the pains in the abdomen and extremities abate; at length convulsions, and a comatose condition ensue, from which very few recover. Cases are recorded by Louis and others, in which death suddenly occurred during the first stage of the disease, without the occurrence of any symptoms that would cause such a result to be suspected. Drs. Elliotson and Copland each relate a case in which death was caused by perforation of the stomach. To a paralytic affection of the muscles of the extremities, as a very common effect of repeated attacks of colica Pictonum, we have already referred; and two cases are related by Dr. Alderson, of Hull, England, in which the disease was attended with paralysis of the nerves of vision; Tanquerel states that this is not uncommon in Paris, the paralysis being attended with dilated and immovable pupils; he met, also, with one instance in which deafness was present, no doubt from paralysis of the auditory nerve.—C.]

In the *treatment* of colic—and especially of the lead colic—the great indication is to get the bowels to act. If the pain of the belly be increased by pressure, if the pulse be at all accelerated, if the face be flushed, and there be the slightest approach to fever, it may be right—it can scarcely ever be wrong—to put leeches upon the abdomen, or even to take blood from the arm. This is a measure of safety as regards the possible existence of inflammation: and if there be no inflammation present or impending, it will tend to remove the spasmodic state of the muscles which goes along with, and perhaps chiefly constitutes, the disease. When there is no ground for suspecting inflammation, external warmth should be applied; diligent friction, with some stimulating liniment; or, what is much better, a mustard poultice, or turpentine stupe. My colleague, Dr. John Wilson, has been very successful in relieving these patients, by putting them into a hot bath, and having a large quantity of the water in which they are immersed thrown gradually into their bowels by means of a proper syringe. The bath presently becomes polluted, to the great solace and refreshment of the patient. It will generally be expedient to give a full dose of calomel and opium; ten grains of the one with two of the other. Sometimes the effect of the opiate is to suffer the bowels to empty themselves; showing that the previous difficulty was probably spasmodic. Usually the calomel and opium will soothe the vomiting, the restlessness, and the pain; and then a full dose of neutral salts, or of castor-oil, or (if these do not succeed) of the last named remedy, castor-oil, quickened by one or two drops of the oil of croton, will produce free evacuations from the bowels; and the patient soon returns to his ordinary state of health. It is sometimes

necessary to repeat this practice, this alternation of purgatives and anodynes: but when once the bowels have been freely moved, the disease, in general, becomes very tractable.

Although I cannot vouch the fact from my own experience, I must tell you that *alum* has been highly praised for its efficacy in saturnine colic. When given every three or four hours in full doses — from a scruple to a drachm — dissolved in some bland liquid, it is said to allay vomiting, to abate flatulence, to mitigate pain, and to open the bowels, with more certainty than any other drug; and to be often successful when other powerful drugs have failed.

I have mentioned hot baths. The late Dr. Pereira and others have recommended that these should be medicated, by dissolving the sulphuret of potassium in the water, in the proportion of two ounces to fifteen gallons, using a *wooden* vessel. This solution renders brown or black, and innocuous, any portion of lead that may be lying on the skin, or (perhaps) exuding through it. "The hands, arms, buttocks, and other parts of the bodies of painters, and workmen in white-lead manufactories, are sometimes completely blackened by the bath; but the blackness is readily removed by a brush." If it be true that the sulphuret of lead is thus repeatedly formed upon the skin in successive baths, the elimination of the poison through that channel cannot be doubted.

At La Charité, in Paris, there is what is called a specific mode of treatment followed. It is complicated and rough, but not a whit more successful than the simpler plan which is universally adopted in this country. You may see it described, if you are curious on the subject, in several of the French books. I think it is given in detail in RATIER'S *Formulary of Hospital Practice*.

Though the *colic* may have been subdued, the cure of the patient is incomplete so long as any of the poison still lingers within his body; and of this there is often authentic evidence in the blue margin of his gums, and in his palsied muscles. The dropping of the wrist, which renders the patient incapable of earning his livelihood, he justly regards as a more serious evil than the temporary pain and constipation of his bowels. With a view to eradicate the lurking poison, full doses of the iodide of potassium should now be given. You may remember that when I was speaking of the mercurial tremor, I brought under your notice the experiments of M. Melsens, which seem to prove that this salt is a specific remedy for the chronic forms of both mercurial and lead poisoning. The theory of its sanative operation recommends itself by its simplicity. The poisonous substance is in intimate union with one or more of the tissues of the body, and is retained there in some form which is insoluble in the animal fluids. The iodide, carried to all parts by the blood, combines with the metallic poison, and forms a new and soluble compound, which is again taken into the blood, and discharged from the body through its natural excretories, and especially with the urine. No good opportunity has fallen in my way of trying the iodide in these cases since I became aware of its alleged virtues. It has, however, been put to the test in this country, and its efficacy and mode of action have been fairly established. Thus Dr. Nicholson, of Redditch, relates an instance in which what he names *plumbism* was plainly marked. The patient was a house painter; he had suffered several attacks of colic; his gums showed the characteristic blue line; and the extensors of his wrists were partially paralyzed. Before he commenced the treatment, Dr. Nicholson tested this man's urine for lead, and could discover none. Then he administered the iodide of potassium; and after a while he again tried the urine, and his reagents testified that it contained lead. The medicine was continued about six weeks, by which time the patient was well, and his urine had ceased to furnish any evidence of the presence of lead. Dr. Parkes has published a precisely similar case. No better corroboration of M. Melsens' doctrines could well be had, or desired.

For helping to restore to the damaged muscles their lost power, electricity has been thought useful, applied in the way of sparks at first, and of slight shocks afterwards, along the muscular parts of the extensors of the fingers. In the electro-magnetic apparatus we have a more accessible, and probably a not less efficacious means, of furnishing the requisite stimulus. It accelerates the recovery to give the hand and fingers the mechanical support of a splint, made for that express purpose, and so contrived that they are kept extended through the greater part of the day.

[In a very interesting report on the diseases produced by lead poisoning, drawn up by Dr. Horatio Adams, of Waltham, Mass. (*See Trans. of the American Med. Assoc.* vol. v. p. 163), we have the following account of the remedies that have been found, by experience, to be the most successful in the treatment of lead palsy.

"The *sulphur bath* is frequently employed in paralysis with marked good effect. The temperature should be about milk-warm, and the patient should remain in it from three fourths of an hour to an hour. This will produce a glow and feeling of general heat. The baths will induce a copious perspiration, and a fine cutaneous eruption, attended by a general itching. This state of things will soon exhaust the patient, the baths consequently should never be continued for a longer time.

"*Electro-magnetism* is a valuable remedy when properly used. The shocks should be conveyed through the paralyzed muscles only; if passed through the entire limb, it will generally do more harm than good, exciting the sound more than the diseased muscles. One pole of the battery should be placed at the origin, the other at the insertion of the muscles about to be acted upon. It should be used daily from ten to twenty minutes, according to the ability of the patient to bear it.

"*Strychnine*.—This alkaloid is the most potent remedy we possess for the removal of lead paralysis. It, together with electricity, seems to keep the diseased muscles as it were alive or excited, and prevent that dormant state which soon results in a rapid diminution of their volume. If this artificial life in the muscles can be kept up at intervals for a few months, or till the system is cleansed from the lead introduced into it, we may reasonably expect the disease to be eventually removed.

"The best mode of administering it is in the form of pills containing one-twelfth of a grain each. The dose should be one pill, given once a day, increasing each dose by one pill, till a sufficient number be taken to produce a slight spasmodic action in the muscles. This dose (whatever it may be) should be repeated daily. In a few days, the patient will begin to move slightly the diseased muscles. The immediate effects of this remedy are generally very disagreeable to the patient, producing a tension of the muscles, and as this subsides, a feeling of exhaustion. Frequently, the patient will be very unwilling to proceed with it. Your committee believe, however, if the remedy be judiciously given, and persevered in for months, that the disease will generally yield."—C.]

It is observable of this disease, as of many, and, indeed, of most others, except certain contagious febrile diseases, that when once it has occurred, it is much more liable to occur again, upon a repetition of the exciting cause, than before. It is of very great moment, therefore, that they who are necessarily exposed to the poison of lead—as painters, plumbers, printers (who handle leaden types), colour-grinders, potters, and glass-blowers (who use the oxide of lead in their respective manufactories), shot-makers, workers in lead mines or lead manufactories, and so on—it is of great importance that these persons should be made aware of the means which are best adapted for their protection against the injurious agency of the poison: and we ought to be able to give them advice in that matter. The rules for their guidance are short and simple; and if carefully observed, I believe they will generally prove successful. They resolve themselves into cautions against the admission of the metal, or its compounds, into the body through any channel.

1. To prevent its introduction through the skin minute attention to *cleanliness* is necessary. The face and hands should be washed, the mouth rinsed, and the hair combed, several times in the day; and bathing and ablution of the whole body should be frequently performed: also, the working clothes should not be made of woollen, but of strong compact linen; and they should be washed once or twice a week at least; and they should be worn as little as possible out of the workshop: and some light impervious cap might protect the head while the workman is at his labour.

2. Care should be taken that none of the poison be admitted into the system *with the food*. The workmen, therefore, should not take their meals in the workroom, and should be scrupulous in cleansing their hands and lips before eating.

3. The entrance of the poison into the air-passages during respiration should be guarded against as much as possible. Masks have been recommended for this purpose: none, probably, would be more convenient or more effectual, than Mr. Jeffry's orinasal respirator.

There is a notion prevalent in some places, which apparently has some foundation, that the free use of fat, and of oily substances, as food, is a preservative against the colic. A physician, near Breda, informed Sir George Baker that the village in which he lived contained a great number of potters, among whom he did not witness a single case of lead colic in the course of fifteen years; and he attributed their immunity to their having lived very much on butter and bacon, and other fat kinds of food. De Haen also was told by a physician, the proprietor of a lead mine in Styria, that the labourers there were once very subject to colic and palsy; but that after they were exhorted by a quack doctor to eat a good deal of fat, especially at breakfast, they were exempt from these disorders for three years. This is a kind of prophylaxis that is very easily adopted.

More recently Liebig has asserted that "the disease called painter's colic is unknown in all manufactories of white lead in which the workmen are accustomed to take, as a preservative, *sulphuric acid lemonade*, a solution of sugar rendered acid by sulphuric acid."

If this be so, the lemonade must protect the system by converting any other salt of lead, which might find entrance, into an *insoluble* sulphate: solubility being requisite to give efficacy to any poisonous substance.

Mr. Benson, the manager of the British white-lead works in Birmingham, states (in the *Lancet*) that he has tried this method of prevention. Under his direction sulphuric acid was first added to the *treacle-beer*, used as a beverage by the workmen, in the summer of 1841. Lead colic, which had prevailed before "to a distressing extent," soon began to diminish in frequency: and from October in the same year, up to the date of Mr. Benson's communication in December, 1842—a period of fifteen months—not a single instance of the disorder had occurred amongst them. This is very encouraging.

[*Encephalopathy*, according to Tanquerel, is a distinct form of disease arising from the noxious influence of lead upon the animal economy, and would seem to depend immediately upon some lesion of the brain. It embraces all the various forms of cerebral affections that have been observed to arise from lead poisoning. The author referred to considers that it requires for its production the absorption of a larger amount of lead particles than is requisite to induce colic, arthralgia, or paralysis. He describes four distinct forms of these cerebral affections: 1, delirium; 2, coma; 3, convulsions; and 4, a combination of delirium, coma, and convulsions.

In the first of these forms of disease, *delirium* is the leading feature. It either assumes the peculiar restless, talkative character of delirium tremens, or the more violent symptoms peculiar to acute meningitis. Two varieties have been described, viz., quiet delirium and furious delirium. In the former of these, the patient is generally quiet, his features and eyes being immovably fixed, with rather an astonished air; his countenance is sometimes composed and thoughtful; at other times his eyes are turned upwards, and his whole expression is that of ecstasy; when spoken to, his answers are at first sensible, but soon his ideas rapidly succeed each other without apparent connection. The patient is by turns either gay or sad, loquacious or silent. He will be in a constant state of restlessness, tossing his arms, and throwing off the clothes, and trying to get out of bed. Sometimes he will be affected with a light trembling, chiefly in the arms and face, and experiences a hallucination of sight and hearing which at times greatly harasses him.

In the second variety, the eyes are widely opened, menacing, furious, or haggard; the features are contracted; the patient cries, shouts, swears, tears his garments to pieces, bursts through the restraints by which he was confined, and, in short, is in a state of complete and raging insanity. The delirium is sometimes accompanied by spasmodic contractions of the muscles of the face, distortion of the eyes, chattering of the jaws, twitching of the tendons, or tremors of the limbs. Notwithstanding all this nervous disturbance, by suddenly fixing the attention of the patient on some very simple question, a rational answer will occasionally be obtained. The progress of both these varieties of delirium is very irregular, varying from instant to instant, without order; but when it is about to terminate favourably, a long, deep sleep supervenes, at the close of which, a complete change is observed, often an unexpected amelioration.

The second, or *comatose* form, is characterized by coma, more or less profound. Tanquerel distinguishes two varieties of this form, according as the coma exists simply, or as it is combined with low delirium. In the former variety the patient is immovable, his limbs are drawn up, and his eyes closed, or half closed; he utters occasionally some heavy groans, turns in his bed, opens his eyes only to close them immediately, and is not easily roused from the comatose state in which he is plunged.

In the latter variety, there is a partial rousing from the comatose state, during which the eyes are opened, and a few unintelligible words are uttered, and a degree of restlessness manifested. "These two varieties of comatose encephalopathy," says Tanquerel, "show themselves alternately or isolated, during all the course of the disease, and observe no order in their appearance or disappearance."

In the *convulsive* form of this disease, Tanquerel distinguishes five varieties: 1. Partial convulsions, in which the face, or one side, or one or more of the limbs, are agitated by repeated quick shocks; or there may be spasms of longer or shorter duration. These symptoms may coexist with delirium and somnolency, or with cephalalgia, more or less intense. 2. General convulsions. The cerebral disturbance, in this variety, may often be attributed to the violence of the colic or arthralgic pains. The convulsive shocks extend to the whole body, affecting the face and superior extremities most severely. They are distinguished from epilepsy by the consciousness being partially retained; the patients being often able to relate, in part, what they have experienced during the fit. Reason generally returns after a quiet sleep. 3. Epilepsy; the most common form in which cerebral disturbance from the deleterious effects of lead evinces itself. The paroxysm lasts from two to thirty minutes, and in no case have any traces of an *aura epileptica* been detected. When the attack is light, the patient suddenly falls, deprived of reason and general sensibility; he does not speak, but sometimes utters groans, and is but lightly convulsed. The more violent attacks are characterized by: "Immediate loss of reason, the globe of the eye being turned up, the head immovable, the face suddenly injected, and, in an instant, the florid red colour changing to the paleness of death. Some convulsive movements pass through the limbs, and the body is stiffened; soon these symptoms acquire a prodigious increase; the hand is clenched, and the thumb turned convulsively within; violent spasmodic shakes agitate the whole body. Respiration is modified by the convulsive state of the muscles of the breast; it becomes short, interrupted, jerking, noisy, and afterwards stertorous; a foaming saliva, often bloody, is thrown out with noise and difficulty." 4. Epileptic convulsions. In this variety, the convulsive contractions are less energetic than in epilepsy; usually, there is no foaming at the mouth, or stertor; the spasms are almost continuous, and may last from one to twenty-four hours. 5. Catalepsy. The appearance of a patient, under this variety, is that of a person in a tranquil sleep; he gives no sign of sensibility or feeling when pinched or even burned, and it is impossible to awake him, or fix his attention. If his fingers, hand, arm, foot, or leg be placed in any position, constrained or easy, they are fixed for some seconds or minutes, then shake a little, and fall upon the bed. This state alternates with one in which there is some restlessness of motion and return of sensation. "After some hours, or entire days of alternations of repose and restlessness, the patient suddenly opens his eyes, feels physical wants, and asks to eat or drink."

In the fourth form of encephalopathy, there is a *combination* of all the symptoms occurring in the three other forms; it presents the type of the disease. The utmost irregularity prevails in the various combinations. Tanquerel gives the following as the most usual and most regular: "The patient is, at first, affected with delirium, sometimes so light that the physician does not recognize it; at the end of some hours, or one or two days, an attack of epilepsy supervenes, in consequence of which, the patient becomes drowsy for some minutes; then he seems to awake, and talks all day; delirium, tranquil or furious, is then more decided than before the fit of convulsions; the same day, the night following, or the next day, one or more attacks of epilepsy supervene again. After each fit, the drowsiness is more profound and long; it is interrupted only for an instant, by a half waking for some minutes, during which the patient murmurs some words, then sleeps again. If the epileptic fit is renewed often, coma becomes very profound, then death takes place. In the contrary case, the patient seems to wake suddenly from his drowsiness, after some hours, or a day."

The encephalic nervous system seems to be the seat of this disease. All the pathological phenomena belonging to it point to alterations in the encephalon. Pathological anatomy, which has shed so much light on all organic affections, has revealed nothing, however, satisfactory concerning lead encephalopathy. If there are organic changes in the brain, they are too subtle to be appreciated by our senses, even with the aid of the microscope.

In regard to the treatment of encephalopathy, Tanquerel says: "At present, the best means known, for preventing the fatal termination of encephalopathy, is the expectant method. The physician who witnesses such violent accidents of the brain, with difficulty resists the desire of prescribing some treatment, in hopes that it will do no harm, and may, perhaps, prevent a fatal termination. It is painful for him to fold his arms before the disease, but experience is the greatest of masters; the facts referred to are sufficiently conclusive to persuade every practitioner that the best mode of treatment, to oppose to one of the most formidable diseases to which man is subject—lead encephalopathy—is that pursued at the "Charity" by Rayer; that is, the expectant method, of which diet and diluted drinks form the basis." C.]

LECTURE LXXII.

Diarrhœa. Sporadic, or Summer Cholera. Epidemic Cholera.

THE morbid *fluxes* which proceed from the long tract of mucous membrane lying between the stomach and the anus are many in number: and they vary much, both in kind and in cause. *Hæmorrhages* are not uncommon. I have already described the disease called *melæna*, which is characterized by the discharge of black semifluid matters, resembling tar, from the bowels, and in most instances from the stomach also by vomiting. The matters vomited, and the matters passed by stool, are composed principally of blood, which has been rendered black, and otherwise modified in appearance, during its progress outwards in the one direction and in the other. Again, hæmorrhage from the bowels is apt to occur in *typhoid fever*; as I shall show you when we come to that disease. Hæmorrhage takes place also from the rectum in *hæmorrhoids*, or *bleeding piles*: a malady that falls chiefly to the care of the surgeon. Blood comes away, too, mixed with a greater or less quantity of mucus, in *dysentery*.

The remaining forms of profluvia from the intestinal canal I shall proceed to consider *seriatim*: at least the most important of them.

There are several very different affections classed together under the head of *diarrhœa*: by which term is usually signified the occurrence of frequent, loose, or liquid alvine evacuations. Thus diarrhœa is a very common symptom of pulmonary phthisis; and this form of the disorder has been already mentioned. It is very often met with also in typhoid fever, and during the decline of the febrile exanthemata, of which I have yet to speak. Stubborn diarrhœa attends malignant disease of the lower bowel. But diarrhœa is not unfrequently the main symptom of the illness under which the patient labours; and constitutes, at any rate, the chief object of our treatment. I shall touch briefly on some of its varieties.

In the first place there is that common form of the complaint which proceeds from over-repletion of the stomach; or from the ingestion of food that is not wholesome: food that disagrees (as the phrase is) with the patient's stomach and bowels at that particular time. We may call it, with Cullen, by way of distinction, *diarrhœa crapulosa*; in which fæces are discharged in a more liquid state, and more copiously, and more often, than is natural. These cases are in truth slight cases of irritant poisoning. The ingesta irritate the mucous surface, and probably the muscular coat also; the secretions into the intestines are poured forth in unusual abundance, and

the peristaltic motions become more strong and active; the object of these changes being that of getting rid of the offending substances: a salutary and conservative effort, which we assist and imitate in our *treatment* of this form of diarrhœa.

The symptoms by which this species of diarrhœa is marked, must be well known to us all. There are often nausea, flatulence, griping pains in the bowels, succeeded by stools of unnatural appearance and odour, and of fluid or watery consistence. There are often, also, a furred tongue, and a foul breath: but the disorder is attended with little or no fever; the pulse remains of the ordinary frequency; and the temperature of the body does not rise.

There are certain things which, more than others, tend when taken into the stomach to cause this crapulous diarrhœa: and there are certain circumstances which increase the disposition to be affected by the ordinary exciting cause.

We frequently see this disorder supervene upon a debauch, in which case the *mixture* of various articles of food, and of drink, each of which in itself might have been perfectly innocent — and the actual *quantity* of the mixed ingesta — have occasioned the irritation and disturbance. But where there has been no intemperance in eating or in drinking, some kinds of food are more likely than others, *cæteris paribus*, to provoke diarrhœa. I do not speak of idiosyncrasies, which show the truth of the old proverb, that what is one man's meat is another man's poison, and which cannot be reckoned upon beforehand; but I refer to the average of systems and stomachs. And among these less-digestible and irritating substances we may place *raw vegetables* of many kinds; such as cucumbers and salads, sundry sorts of fruit, especially if they are hard, immature, and acid; plums, melons, pine-apples, nuts, and so forth. Mushrooms may be added to the list, even when they are cooked. *Putrid* food, or food which, in the more refined phraseology of gastronomers, is termed *high*, has the same effect upon some persons: and so, in a particular manner, have some kinds of *fish*; shell-fish, crabs, and muscels for instance, in this country: and in other countries, in the West Indies, there are several species of fish which are actually poisonous, and cannot be safely eaten at all. And similar disorder is frequently produced in children by any sort of food, other than the natural sustenance furnished by the mother. The new kind of nutriment disagrees with them: and the very same thing is apt to occur in adult persons. An article of diet which is perfectly wholesome and digestible, and which the stomach bears well after a little habit, will sometimes cause griping and purging, when it is taken for the first time. It is upon this principle that the diarrhœa to which Englishmen are subject upon their first visiting the towns upon the continent, is to be explained. I do not know that it is so, but I think it very likely that Frenchmen, and Germans, and Italians, suffer in the same way when they first come to this country, and adopt our habits and regimen.

Another curious exciting cause is to be found in certain *mental emotions*, and especially the depressing passions: grief, and above all, fear. A sudden panic will operate on the bowels of some persons as *surely* as a black dose, and much more *speedily*. Among the circumstances which *predispose* most persons to this kind of malady, we may particularly specify *season* — the hot weather of summer and autumn. And it is probably consistent with the experience of most of you, that the atmosphere of the dissecting-room has a similar tendency.

Now this diarrhœa, from occasional irritation, produced by the presence of substances that offend the stomach or bowels, will generally cease of itself. The purging is the natural way of getting rid of the irritant cause. We may *favour* the recovery by diluent drinks, and by making the patient abstain from all further use of food which is not perfectly easy of digestion; and we may often *accelerate* the recovery by sweeping out the alimentary canal by some safe purgative, and then soothing it by an opiate. Or we may give the aperiant and the anodyne together, and the one will not interfere with the operation of the other. A table-spoonful of castor-oil, with six or eight minims of laudanum dropped upon it: or from fifteen grains to a scruple of powdered rhubarb, with half as much of the *pulvis cretæ compositus cum opio*. By some such medication as this, emptying the bowels, and quieting them, the cure is generally accomplished with ease, and speedily: *tutè, citò, et jucundè*.

We sometimes however meet with cases in which diarrhœa *runs on*: the stools being composed of fecal matter in an unnaturally fluid state; and the precise condition on which this disposition to an over-loose state of the bowels depends, escaping

detection. If the disorder be slight, it will often yield to the astringent and bitter medicines. The infusion of cusparia, with the tincture of cinnamon, may supply a convenient formula. If it be more severe, or obstinate, we have recourse to chalk mixture, which neutralizes acidity; combined with catechu, or with rhatany, which are direct astringents of the tissues; and with laudanum, which calms irritation. And in extreme cases the sulphate of copper has been found to have a powerful effect in restraining the flux. It is apt to gripe, and should be combined therefore with opium. A quarter of a grain of each, in a pill, given three or four times a day, I have frequently found successful, when previous attempts to remove the diarrhœa had failed. Tannin is another substance which is often effectual in arresting chronic diarrhœa; and it is very useful in cases where opium is not well borne. Three or four grains of it may be given at intervals of four or six hours.

[A much more effectual remedy is the acetate of lead, combined with opium and ipecacuhana; one grain of the first, from a fourth to the half of a grain of the second, and from half a grain to a grain of the latter, combined in the form of a pill, or in a powder, mixed with a little simple syrup, may be given to an adult, and repeated every three or four hours according to circumstances.

Diarrhœa in a chronic form is that which the practitioner will be most frequently called upon to treat in the adult; and it, in general, requires for its complete removal a cautious and judicious course of treatment, persevered in for a length of time. The slightest deviation from the strict diet and regimen required in each case, will often very considerably protract the cure, while a too early abandonment of the appropriate remedies will frequently be quickly followed by a return of all the worst symptoms of the disease.

In chronic diarrhœa there exists a morbid excitability of the intestinal canal, so that almost everything taken into the stomach, as food or drink, brings on quickly repeated discharges by stool consisting of the ordinary secretions of the digestive tube, more or less changed in character, mixed with portions of half digested aliment; and the looseness continues, often unattended with griping, or any other uneasy sensation save those connected with the debility and emaciation produced by the interruption to the digestive and nutritive functions generally, which the rapid passage of the aliment through the bowels occasions. There is no doubt, that frequently the morbid excitability of the digestive canal is due to a chronic inflammation, often follicular, and attended with ulceration of some portion of its mucous membrane; when this is the case, we have repeated discharges by stool, without apparently any exciting cause other than the morbid secretions of the liver, pancreas, or of the stomach and intestines themselves. The discharges are, in general, dark-coloured and offensive, very fluid, and small in quantity, and are often preceded and accompanied by griping pains more or less severe. There is, very commonly, some degree of nausea, and occasionally vomiting; the appetite for food is generally destroyed, though in many cases it continues unimpaired. The patient becomes more and more emaciated and debilitated; his skin assumes a dirty sallow hue and a dry harsh feel; the palms of his hands become hot and dry; his countenance has, in many cases, a dull, desponding expression; his features acquire considerable sharpness, and his eyes become sunken and surrounded by a broad leaden-coloured ring. The abdomen is frequently flaccid, and exhibits no tenderness upon moderate pressure; occasionally, however, it becomes swollen and tympanitic, and is now and then decidedly tender to the touch. We have known in cases of chronic diarrhœa, an effusion of serum to occur within the peritoneal cavity, and to produce a very decided intumescence of the abdomen. In protracted cases, the body exhales a peculiar sickly odour, the tongue becomes of a dark mahogany hue, and often, together with the parietes of the mouth, is covered with aphthæ. The pulse is usually small and feeble, often quick and frequent. Febrile symptoms are not generally present; in many cases, however, there is observed some degree of febrile excitement towards evening — very protracted cases we have repeatedly known to be accompanied with well-marked hectic symptoms. More or less puffiness of the face, and œdematous swelling of the extremities, very commonly occur in the course of the disease. The discharges by stool, while they are always fluid and vitiated, exhibit considerable variety in their appearance; most generally they are dark-coloured, and exhale a rancid or fetid odour; occasionally, however,

they have a jelly-like consistence, and very little smell; at other times they consist of a small quantity of a dirty yellow fluid, and when they contain solid matter this will generally be found to consist of portions of half-digested aliment. All these changes in the character of the discharges may present themselves in the same case, and often within a very short period. In protracted cases, the discharges would appear to acquire an acrid property, producing an erythematous inflammation of the verge of the anus, and often of the nates. The frequency of the stools varies very much in different cases, and at different periods in the same case. Occasionally, the diarrhœa takes place only after the ingestion of food or drinks, or of particular kinds of food, and the discharges from the bowels continue to recur at short intervals until the offending matters are got rid of. In many cases, repeated stools occur in the course of the day, whether food is taken or not, and are suspended during the night; in other instances, the evacuations from the bowels often cease for a day, or even longer, and then return, and for a short period with increased frequency.

The duration of chronic diarrhœa is very various; unless arrested by a proper course of treatment—its spontaneous cessation being a thing of very rare occurrence—it will run on for weeks, often for months, and the patient finally sinks from extreme exhaustion. Occasionally perforation of the intestines occurs from ulceration or softening, and the fatal event is preceded by peritonitis.

The causes of chronic diarrhœa are the same as those of the acute or simple form of the disease. Frequent attacks, within a short period, of an ordinary bowel complaint, will very commonly induce a chronic affection.—Improper articles of diet, and acescent drinks, habitually indulged in; exposure to a cold, and, at the same time, humid atmosphere; the abuse of purgatives, and intemperate habits generally, are among the most common causes of chronic diarrhœa. It is an affection much more readily induced in those of a lax, and feeble, excitable and broken-down constitution, than those of an opposite condition.

The state of the intestinal tube in those who have fallen victims to the disease is very various. In some cases, the mucous coat, particularly of the large intestines, is somewhat thickened, spongy, and pale—in others its anatomical characters are entirely changed, large portions of it presenting a smooth, glassy, mottled appearance, as though its surface had been covered with a thin coating of dirty varnish. Occasionally, large patches of the mucous membrane of the colon or rectum are of a dark mahogany or of a slate colour. Traces of follicular inflammation, or of ulcerations, more or less extensive, are not unfrequently met with, especially in the ileum and colon. Dr. Stokes notices a form of chronic diarrhœa as of common occurrence, dependent upon ulcers situated close to the verge of the anus; these ulcers occur chiefly in persons of a broken-down constitution, and those who have taken a great deal of mercury; we have repeatedly observed them, also, in individuals, who have been in the habit of using almost daily the various pills composed chiefly of aloes, soap, and scammony, or gamboge, of which vast quantities are vended in the United States as a popular remedy for almost every ailment. The ulcers situated just within the anus produce irritation in the colon, tenesmus, griping, frequent discharges by stool, and most commonly, during the straining, a little blood is passed. The presence of the ulcers may be at once detected by an examination of the rectum; which examination, as Dr. Stokes very correctly remarks, should invariably be made in all cases where the diarrhœa has been of long standing, and has resisted a great variety of treatment; where it is attended with tenesmus, and a desire of sitting on the night-chair after a stool has been passed; and, finally, where the patient's health does not appear to be so much affected as it naturally would be from long-continued disease of a large portion of the great intestine.

In the treatment of chronic diarrhœa our leading indications are, to control the morbid irritability or excitability of the intestinal mucous membrane, and restore it as quickly as possible to its healthy condition and functions. To effect these objects is not always, however, a very easy task; it is one which always demands considerable judgment on the part of the practitioner, and considerable patience, and an implicit obedience on the part of the patient to the medical directions and dietetic rules laid down. The first and all-important consideration is that of diet—so that, while the patient is supplied with aliment calculated for his support, as little irritation as possible of the intestines shall be excited by it. The food taken by an individual labour-

ing under chronic diarrhœa should be easy of digestion, of the mildest quality, and such as leaves, after undergoing digestion, but a small quantity of excrementitious matter; and even of such food but a small portion should be taken at a time. Rice is probably the best article of diet in the generality of cases of chronic diarrhœa; when well boiled, with the addition of a little salt, while it is sufficiently nourishing it is extremely mild and unirritating, by no means difficult of digestion, and scarcely affords any excrementitious matter to be transmitted along the intestines. It may, generally, be eaten mixed with a very moderate quantity of plain beef or mutton broth. Plain meat broths, prepared with the addition of a large amount of rice, will often furnish a very suitable food in chronic diarrhœa, and are to many stomachs more palatable; rice, also, boiled with milk and sweetened, but not too heavily, with the best of loaf sugar, or fresh milk thickened with rice flour, may be occasionally given. Should either preparation, however, be found to disagree with the patient, or to augment or keep up the diarrhœa, it should be at once relinquished. We have indeed, in numerous instances, found plain broths, when well prepared, or the juice of roasted meats, with a portion of stale bread or cracker broken into it, agree better than any preparation of rice. Tapioca, sago, or arrow-root, we have seldom found an appropriate aliment for persons labouring under the chronic form of diarrhœa. As soon as it can be borne, and this can only be ascertained by a cautious trial, a small portion of tender chicken, turkey, or mutton, plainly boiled or roasted, may be eaten with rice. Pure water, toast water, or rice water, taken cold, and in very moderate quantities at a time, should be the only drink allowed.

Next, or more properly perhaps, equal in importance to a well-regulated diet, is an attention to the clothing and regimen of the patient. Individuals affected with chronic diarrhœa, are particularly susceptible to the influence of a cold and damp atmosphere—a slight exposure to which will often increase their disease, or when we have succeeded in diminishing the frequency of the discharges, will cause them to return as before. It is essential, therefore, that independent of cautiously avoiding every species of exposure, the patient should be suitably lodged and clothed. The chamber he occupies at night, as well as during the day, should be dry, of a comfortable and equable temperature, perfectly clean, and well ventilated. His clothing should be adapted to the season and state of the weather—flannel next the skin should always be worn; a belt of flannel round the abdomen, or enveloping this part with a flannel roller nicely adjusted, and renewed daily, will always be found advantageous. In obstinate and protracted cases, the removal of the patient from a cold, damp, and changeable, to a more equable, warmer, and drier climate, whenever practicable, is a measure from which the very best results are to be anticipated; it has, in numerous instances, been known to effect a speedy cure, when all other means have failed.

In regard to exercise, even the gentlest kind, whether passive or active, cannot sometimes be taken, from the frequent and pressing calls to evacuate the bowels which occasionally are found to be excited by motion of every kind: in other cases, short walks in the open air, in suitable weather, or a gentle ride in an open carriage, or sailing in a boat, are advantageous, and should be repeated daily if the patient's strength will admit of it.

The warm bath, followed by brisk friction of the surface, is a remedy from which the best effects are to be anticipated in most cases of chronic diarrhœa; it may be repeated daily, the temperature of the water being carefully graduated by the condition of the patient's surface; when this is dry and warm, a tepid bath should be preferred, but if the surface is cool, or its heat is not well sustained, the water should be decidedly warm. The temperature of the bath should never be so low as to cause the patient when immersed in it the slightest sensation of chilliness on the one hand, nor so high on the other, nor the continuance in it so long, as to produce profuse perspiration.

By a few physicians the effects of leeches to the abdomen or to the anus, in cases of chronic diarrhœa, are spoken of in the highest terms of commendation. Drs. Crampton and Forbes, in their very excellent essay on the disease under consideration, contained in the *Cyclopædia of Practical Medicine*, (*Philadelphia Edition*, vol. i., p. 640,) speak of leeches applied to the anus, as a remedy “possessed of remarkable powers—often working,” according to the common expression, “like a charm, even in cases of diarrhœa of *very long standing*, and of different external characters.

Combined with proper diet, indeed, we are persuaded," they remark, "that the greater number of diarrhœas, *both acute and chronic*, will yield to this method, with little or no aid from other medicine."—"Although, in our practice, we always," they add, "combine with the use of leeches, in the cases where they are indicated, a proper diet, yet we have had ample evidence of their unassisted powers in checking or removing diarrhœa of great severity and obstinacy."

It is certain that most of the more obstinate cases of chronic diarrhœa are kept up by a subacute inflammation of some portion of the mucous membrane of the large intestines, and in such cases a well-timed application of leeches to the anus will be productive of the best effects. In such cases, the earlier the leeches are applied the better. In detecting the cases in which leeching is indicated, will demand a good deal of tact, and close habits of observation on the part of the practitioner—his judgment must be made up from an inquiry into the history, and a careful analysis of all the circumstances of each case, for we know of no leading phenomena by which those cases where leeches are calculated to do good can be distinguished from those to which they are not adapted; as a general rule, however, we are persuaded that in well-marked cases of chronic diarrhœa, particularly when the disease has existed for any length of time, leeches are at best a doubtful, if not an improper remedy.

Blisters to the abdomen will, we apprehend, be found more generally advantageous than leeches; we have found them to produce a speedy, marked, and prompt amelioration in the prominent symptoms of the case; the frequency of the stools, under their use, being speedily diminished, and the discharges assuming a more natural appearance. In many instances, however, we confess that no benefit whatever has resulted from repeated blisters. They are a remedy, nevertheless, which so generally do good that they should not be overlooked. Keeping on the blister for a few hours, and then replacing it by a soft emollient poultice; repeating it as soon as the vesicated surface has healed, is a preferable plan to allowing the blister to remain on until complete vesication is produced, and keeping up the irritation thus produced by stimulating dressings.

The principal internal remedies from which any good effects are to be anticipated are, opiates and astringents. Opium, either by the mouth, or introduced into the rectum, in the form of an injection, acts beneficially by quieting the pain and other uneasy sensations under which the patient labours, as well as by allaying the irritability of the bowels, and thus suspending the frequency of the stools; it aids in this manner the efficacy of whatever astringent is made use of. The Dover's powder will frequently be the best form in which the opium can be administered; or, if this be found to disagree with the stomach, as will sometimes be the case, the opium may be given in the form of a pill; combining it with a small portion of ipecacuanha, we have generally found advantageous: or the opium may be given as an enema rubbed up with starch. The dose of the opium, and the period of its repetition, must be left to the judgment of the practitioner. We have not derived the same advantage in cases of chronic diarrhœa, from the salts of morphia as from the opium itself.

Of astringents, nearly the whole list, both vegetable and mineral, has been recommended, and each one is praised by different practitioners as particularly efficacious in the disease under consideration. The vegetable astringents most deserving of attention are, the catechu, kino, galls, logwood, blackberry root, and the root of the geranium maculatum. The first may be given in the form of the infus. catechu comp. Dr. Pemberton prefers the kino to all other astringents, in chronic diarrhœa; he gave it in doses of a scruple made in a bolus with opiate confection (on *Diseases of Abdom. Viscera*). More recently, an extensive series of experiments on the effects of kino in diarrhœa were made in the hospital *La Pitié*, in Paris, by M. Bally. In chronic diarrhœa, unaccompanied by fever or marks of inflammation in the mucous membrane, the continued use of the remedy, even for a short time, was found almost invariably to be effectual in stopping the diarrhœa. In one case of three years' standing it effected a cure. But the most remarkable result of M. Bally's experiments is the alleged fact—that the kino, given in doses of twelve or fifteen grains, for several days in succession, succeeded in curing diarrhœa attended by febrile and inflammatory symptoms. (*Crompton and Forbes, from Med. Gazette*, v. 700.) We have repeatedly employed both the catechu and kino in cases of chronic diarrhœa where astringents were evidently indicated, and although their beneficial effects were often

promptly exhibited, they have, nevertheless, repeatedly failed in diminishing the frequency of the discharges. We have found the galls, either in powder—combined with camphor or opium, and not unfrequently with both—or in decoction, a much more effective astringent in protracted and obstinate cases of diarrhœa, than either the kino or catechu. The logwood in decoction is a favourite remedy with many practitioners; we have, however, been disappointed in its effects; it may serve as a useful vehicle for more active remedies. The dewberry-root is unquestionably a very powerful astringent, and well adapted to the disease under consideration; in infusion or decoction it is extensively employed by the physicians of the United States, as is also the root of the *geranium maculatum*, the effects of which latter, in chronic discharges from the bowels, are very highly spoken of by many practitioners.

Of the mineral astringents, we know of none superior, in cases of chronic diarrhœa, to the acetate of lead; in the dose of one grain, combined with a quarter of a grain of opium and the same quantity of ipecacuanha, repeated every three hours, it will, in a large number of cases, promptly arrest the disease. The alum will, also, be found a good astringent in chronic diarrhœa; it may be administered in the form of alum whey, or in substance, combined with opium. We have given it in conjunction with powdered galls and with the best effects. The sulphate of copper, which has been employed in combination with opium by Dr. Elliottson with the most decided success, has repeatedly succeeded in our hands in arresting the disease under circumstances the most unpromising. The mode in which we have generally employed it, has been in a quarter or one-third of a grain doses combined with two grains of extract of quinia and a fourth of a grain of opium every three hours. The protoearbonate of iron, the tincture of the chloride of iron, or the ammoniated tartrate of iron, and the solution of the persesquinitrate of iron, we have repeatedly employed, and in cases of long standing have found them, especially the first three, very efficacious. They are particularly well adapted to protracted cases of the disease, attended with great prostration, and more or less infiltration of the subcutaneous cellular tissue.

The balsam copaiba and spirits of turpentine are among the remedies from which, in numerous cases of chronic diarrhœa, the very best effects may be anticipated. When the discharges from the bowels are small in quantity, and resemble in consistence thin starch or mucilage, or when they are dark-coloured and of a rank offensive odour, we are acquainted with no remedies from which the same amount of good may be anticipated. They may be combined with opiates and astringents where these are considered necessary. The spirits of turpentine we employ more frequently than the copaiba; it is, we believe, equally efficacious, while it is more easily taken by the patient, and agrees better with the stomach: it may be combined with simple syrup and water, by adding a few grains of calcined magnesia.

A variety of other remedies are recommended by different writers, the efficacy of which is highly extolled. The most prominent are *Hope's Mixture*, which is a mixture of nitrous acid, camphor water and laudanum—the *nux vomica* and its active principle; the ferrocyanuret of iron; the nitrate of silver, and the resinous extract of the *artemisia vulgaris*. Of the effects of these we have had no experience.

In those cases in which the diarrhœa appears to be kept up by ulceration seated just within the verge of the anus, very speedy and permanent relief will always be obtained by touching the ulcers with nitrate of silver.

We have given above an outline of the treatment demanded in the chronic form of diarrhœa; in conclusion, we would remark, that the management of this disease always requires the exercise of great judgment and discretion on the part of the practitioner. Nothing would appear more easy than by opiates and astringent remedies to arrest the inordinate discharges from the bowels, and thus to effect the cure of the patient, but it will be found that, in many cases, when astringents are too early resorted to, the disease, instead of being removed, is aggravated; or if by our astringents we do succeed in suspending the discharges from the bowels, a swollen and painful state of the abdomen quickly succeeds, producing greater distress to the patient, and terminating more promptly in death, than had the diarrhœa been allowed to run its course. In numerous instances, chronic diarrhœa may be very effectually cured by a proper regulation of diet and regimen, the warm bath, blisters to the abdomen, and internally the blue pill, or calomel combined with opium and ipecacuanha, and, perhaps, the use, at the same time, of moderate doses of copaiba or turpentine, without

astringents. There are, however, unquestionably, many cases, in the course of which astringents, and of the most powerful kind, are demanded in order to effect a removal of the disease, and others, in which mild astringents, early administered, will very materially shorten its duration; and it is in rightly determining the cases and period of the disease, in which astringents are indicated, that the success of the practitioner in effecting its cure will frequently depend.—C.]

I have alluded to the influence of *hot weather* in predisposing the system to be affected by the exciting causes of diarrhoea. Dr. Farr remarks that diarrhoea “is as constantly observed in English towns when the temperature rises above 60°, as bronchitis and catarrh when the temperature falls below 32°.” And there is a complaint — of which diarrhoea is one prominent symptom, but which is something more than mere diarrhoea—that shows itself in this country more or less every autumn, and prevails extensively in some years, as a minor epidemic. It is rightly enough named *cholera*; for it is attended with, and consists mainly of, a remarkable flux of *bile*. Sydenham held that the disease is limited to the month of August: and that bowel affections, with vomiting, occurring at other times, are not genuine cases of cholera. But this was one of that great man’s crotchets. The symptoms that mark this complaint are vomiting and purging of liquid matter, deeply tinged with, and principally composed of, bile; violent pains in the stomach and bowels; cramps of the legs and of the abdominal muscles; a great depression of the vital power, and a tendency to syncope or collapse.

The attack is generally sudden. At first the contents of the alimentary canal are evacuated; and then a quantity, an enormous quantity sometimes, of a turbid, yellowish, acrid fluid is expelled with violence both from the bowels, and by vomiting. The patients complain of a burning sensation in the epigastrium. As the vomiting and purging go on, clonic spasms of the lower extremities, and especially of the gastrocnemii, occur; the surface of the belly is drawn up into knots: and after a while, the patient, exhausted by the pain and the spasms, and still more by the copious discharges, grows cold and faint. Sometimes actual syncope happens: and sometimes death.

Death, however, is an uncommon event of this form of cholera, in this country.

The chief cause of cholera, such as has now been described, appears to be casual exposure to cold, after a continued high temperature of the atmosphere: and the great irritation of the stomach and bowels evinced by the symptoms, proceeds from the presence of bile in the intestines in undue quantity, and rendered more acrid than usual by some morbid alteration of its quality. The attack seems to be often determined by some of those causes of irritation which I just now mentioned when speaking of simple diarrhoea: and particularly by imprudence in eating and drinking.

I believe that no better *treatment* can be followed in this disease than that long ago laid down by Sydenham. He observes that any attempt to stop the purging and vomiting by strong drastic aperients, under the notion of expelling the irritant matter, would be like endeavouring to extinguish fire by pouring oil upon it; and that to try to lock up the acrid discharges in the alimentary canal by means of narcotics or astringents, would be equally hurtful. He therefore was accustomed to dilute the contents of the stomach and bowels by emollient drinks, and injections, especially by chicken broth; and so to favour their expulsion: and when any faintness or sign of sinking began to show itself, to administer *laudanum* in full doses. We are seldom summoned to these cases in the outset. Generally the vomiting and diarrhoea have continued for some hours before we see the patient; so that it is expedient to give the opiate as soon as we can. If the stomach be very irritable, solid opium in the form of pill may be preferable to laudanum; or an opiate clyster — or an opiate suppository — may be introduced into the rectum.

[In such cases we know of no remedy more effectual than a pill composed of opium, camphor and acetate of lead, in the proportion of one grain each. When the stomach is so irritable that the pill is quickly rejected, a solution of acetate of lead, eight grains to two ounces of water, with the addition of one grain of the acetate of morphia, in the dose of a teaspoonful, repeated at proper intervals, will very generally be retained.—C.]

When the skin is cold, and the pulse sinking or irregular, carbonate of ammonia, or brandy and water, may be given by the mouth: and a mustard poultice, or a bag of hot salt, or a moist and hot flannel sprinkled with oil of turpentine, should be applied to the abdomen. The cramps of the extremities may be relieved by diligent friction with the hand; or some stimulating liniment may be rubbed upon the affected muscles. When the collapse is great the patient should not be allowed to raise himself out of the horizontal posture, lest fatal syncope should follow. Opium, however, is our sheet-anchor in this complaint: it sustains the flagging powers, while it quiets the gastro-intestinal irritation.

After an attack of severe cholera, the patient is apt to be left extremely feeble; with soreness of the muscles of the trunk and limbs: and sometimes, symptoms of *inflammation* of the mucous membranes will supervene; pain and tenderness of the belly, a white tongue, thirst, and fever. And these symptoms may require some of the *remedies* of inflammation.

Such is the disease which has long been familiar to English practitioners, as *cholera*: but about the end of the first third-part of the present century, this country was visited by a severe epidemic disorder, which was also called cholera; or by way of emphasis, *the cholera*; or sometimes *spasmodic cholera*; or *Asiatic cholera*; or *malignant cholera*. The symptoms of this new disease resembled, in some points, those of the old-fashioned cholera: but differed from them in more, and in more important, particulars. So that the application of the term cholera, or cholera morbus, to both these morbid conditions, is very much to be regretted, for it has produced a great deal of confusion and inconvenience.

I scarcely know how to name the newer and severer disorder. I have no right to alter the received nomenclature; and choosing from among the many appellations which have been given to the complaint, that epithet which seems the least objectionable, I may call it *epidemic cholera*: although this term is not unobjectionable, since the other malady, to which Dr. Farr has given the appropriate name of *summer cholera*, is sometimes also epidemic.

The *epidemic cholera* so far resembled the *summer cholera*, that it was attended by profuse vomiting and purging, by extreme prostration of strength, and by cramps. But it differed remarkably in *these* respects; in the circumstance that the matters ejected from the stomach and bowels contained no bile (and this alone is a good reason against calling the disease *cholera*); in the early supervention of the symptoms of collapse; and in the great mortality of the disorder.

The amount of the fluid matters thrown up from the stomach and discharged by the bowels, was really in many cases wonderful. At first, perhaps, the patient would have so copious a stool—a consistent dejection it might be, but so large in quantity—as to lead him to conclude that the whole contents of the intestines had been evacuated at once. Yet soon afterwards a turbid whitish liquid would again and again pour from his bowels in streams, and be spouted from his mouth as if from a pump: not in general with pain or much effort, but easily and abundantly. The matters thus discharged were thin, and for the most part of a whitish colour, like water in which rice has been boiled; without faecal smell; and containing small white albuminous flakes. There were some varieties in the evacuations, but the kind I have mentioned, resembling rice-water, was the most common and the most characteristic: and however *else* their sensible qualities might vary, *this* circumstance was universal, that they contained no *bile*.

With all this there was early sinking, and collapse, as it was called. This term *collapse* expressed a general condition, made up, in the most exquisite cases, of the following particulars:—A remarkable change took place in the circulation, and a striking alteration in the appearance of the patient. The pulse became frequent, *very* small and feeble, and at last, even for hours sometimes, extinct at the wrists. The surface grew cold; and in most, or in many instances, blue as well as cold. The lips were purple; the tongue was of the colour of lead, and sensibly and unpleasantly cold to the touch, like a frog's belly; and the breath could be felt to be cold. With this coldness and blueness there was a manifest shrinking and diminution of the bulk of the body. The eyes appeared sunk deep in their sockets; the cheeks fallen: in short, the countenance became as withered and ghastly as that of a corpse. The cada-

verous aspect that sometimes precedes death in long-standing diseases, would come on in the course of an hour or two, in this complaint. If the physician left his patient for half an hour, he found him visibly thinner on his return. The finger nails became blue; the hands and fingers shrivelled, white, corrugated, and sodden, like those of a washerwoman's after a long day's work. The skin was bathed in a cold sweat. The voice became husky and faint. So peculiar was this change, that the sound was spoken of as the *vox cholERICA*. These are the symptoms which the single word *collapse* was meant to express.

Another very striking feature of the disorder was the muscular cramp; affecting the muscles of the thighs and calves of the legs, rendering them as hard and rigid as wood; and drawing up into knots the muscles of the abdomen. These spasmodic contractions were attended with severe pain, and constituted the greater part of the patient's suffering. During the continuance of the symptoms that I have been endeavouring to describe, not a drop of urine was passed or secreted. One man who was under my own observation and care, and who recovered, did not void a drop of water from Sunday morning till the afternoon of the following Wednesday.

Even in the extreme state of collapse the intellect remained quite clear: the patients would continue to talk rationally to the last moment of their lives; and, for the most part, they seemed singularly indifferent and apathetic about their condition.

In the fatal cases—and a very fearful proportion of the whole number *were* fatal—death took place sometimes in the course of two or three hours; and it was seldom delayed beyond twelve or fifteen. In those that recovered, the favourable symptoms were the cessation of the vomiting, purging, and cramps; the return of the pulse, of the voice, and of warmth to the surface; the disappearance of the blueness of the skin, and of the hippocratic countenance; the reappearance of bile in the alvine evacuations; and the restoration of the secretion of urine.

The course of the symptoms varied a good deal in different persons. Sometimes the vomiting and purging soon ceased, and sometimes there was neither sickness nor diarrhoea at all, but rapid collapse and sinking. These were thought the most formidable cases. However, the peculiar secretions were *poured forth*, in some, at least, of the instances in which none of them were *ejected from the body*. A patient died of cholera in the Middlesex Hospital without any vomiting or purging: but on examining the dead body, we found the intestines quite full of the rice-water serous fluid. Sometimes the cramps were not very troublesome. The cutaneous blueness was not a universal phenomenon. The patients were in general tormented by thirst: and when attempts were made to bleed them, the blood was found dark and thick, like treacle, and scarcely moving, if moving at all, in the veins: in some cases it could not be made to flow out. Considerable hurry and anxiety of the breathing were also symptoms that I omitted to mention before.

Examination of the dead bodies threw no light, that I know of, upon the nature of this frightful disease. The alimentary canal generally was found to contain a white liquid, having whiter flakes in it; such as had previously issued from the bowels: and the mucous glands of the intestines, both the solitary and the agminated, were unusually large and conspicuous. The veins were loaded with thick, black, tar-like blood; and the urinary bladder was always found empty, and contracted into the size of a walnut. Even when the blue colour had existed in a marked degree during life, it often quickly disappeared after death. And another most singular phenomenon was occasionally remarked in the dead body. A quarter, or half an hour, or even longer, after the breathing had ceased, and all other signs of animation had departed, slight, tremulous, spasmodic twitchings and quiverings, and vermicular motions of the muscles would take place; and even distinct movements of the limbs, in consequence of these spasms.

The disease, of which I have drawn but a faint outline, was not known in this country till the autumn of the year 1831. There are persons, I am aware, who hold that it has always existed among us; only not in such numerous instances as at that period; and they appeal to Morton, and other early writers on the diseases of this country, in support of their opinion. But the malady was too striking to be overlooked, or ever forgotten, by any one who had once seen it. Certainly, till that year, I never saw anything like it. To be sure I had not at that time been very many years in practice here. The late Dr. Babington, however, told me that it was quite

new to *him*. He had, for a very long period, been in extensive business, in those parts of the metropolis and its vicinity where the epidemic cholera raged most; and when it first came among us he had the curiosity to ask every medical man whom he met, whether he had seen any case of the cholera; and if the answer were "*yes*," he went on to inquire whether, before that year, the person had ever met with the same complaint; and the reply was always, without a single exception, "*no*." Yet I say there were, and are, a few practitioners who denied, and deny, that it was anything more than the common and well-known English complaint, raging with unusual frequency and violence.

But we have evidence of a different kind of the newness of the epidemic cholera to these kingdoms. Its approach was discerned afar off, as distinctly as a storm is foreseen by the rising of the clouds from the horizon in the direction of the wind. The disorder began to rage with terrible severity, in the Delta of the Ganges, in the year 1817. I do not mean that it then broke out there for the first time. It had again and again desolated those regions before. But from its irruption in the year I have mentioned, when it committed frightful devastation in our armies in the north-eastern districts of India, its course can be distinctly traced to our own shores; towards which it approached with slow and halting, but with sure steps, in a north-western direction. From India it spread to Persia; from thence to Russia; and across through Poland to Germany: and at length it was found at Hamburg. It was predicted before that time, that the distemper *would* at length reach Great Britain. Our government had even sent two physicians into Russia to meet it, and to investigate its nature, in the fearful anticipation that its march across the earth would continue progressive; and accordingly, at the expiration of fourteen years, it made its appearance on the *eastern coast* of this country; in Sunderland: and in due time extended over every part of these islands. I say its arrival had been *foreseen* and *foretold*; and it is absurd to suppose that a vast number of persons would fall sick, and die, with symptoms quite strange to the great mass of practitioners here, merely to fulfil this prediction.

The progress of the disorder did not end here. Crossing the Atlantic, it invaded America; turning, at the same time, in a south-easterly direction, it ravaged France and Spain, and the north coast of Africa, and Italy.

Moving thus onward, as it did, in defiance of all natural or artificial barriers, under opposite extremes of season, temperature, and climate, in the teeth of adverse winds, over lofty mountain chains, across wide seas, through "hot, cold, moist, and dry"—in what manner, you will probably ask, was this wasting pestilence *propagated*?

Upon this point various and discordant opinions are entertained. Many persons believe that the complaint spread by contagion: more, however, that it was not contagious at all, but arose from some deleterious cause with which the general atmosphere of the place was pregnant. Now I cannot reconcile the phenomena of the appearance and extension of the malady with either of these hypotheses, *exclusively*. It must, I think, be granted that the complaint, in every instance, was excited by the application of some noxious material to the body, some positive poison. It is certain, also, whichever hypothesis may be chosen, that many more individuals were exposed to the agency of this poison, than were injuriously affected by it. This exemption from the disease no more invalidates the doctrine of contagion, than it invalidates the doctrine of some diffused atmospheric influence: nay it is more explicable upon the former than upon the latter supposition; for while many may avoid a specific contagion, all are immersed in, and all breathe, the common atmosphere. But the exemption shows *this*: that the exciting cause, to be effective, required a fit recipient; that the susceptibility of being hurt by the poison in its ordinary dose and intensity varied much in different persons; and in the majority was very faint, or wanting. It is clear that the poison travelled. It is equally clear to my mind, that it was *portable*; and therefore communicable from person to person. I even believe that it was capable of being conveyed, and was actually conveyed from one spot to another, by persons who were themselves proof against its effects; or who, at any rate, were unaffected by it. The innumerable authentic instances of coincidence, in point of time, between the first outbreak of the disorder in a particular place, and the arrival at that place of some person or persons from an infected locality, prove that the poison could be thus carried. Of this direct importation of the disorder into new and dis-

tant places, by infected individuals, and of its subsequent extension from those individuals to others who had intercourse with them, you may see a vast number of examples collected by Dr. James Simpson, in the 49th volume of the *Edinburgh Medical and Surgical Journal*. The evidence there adduced of the portability of the poison is abundant, and to my mind irresistible. Whether the malady was contagious in the same sense in which small-pox is contagious—whether, I mean, the cholera poison had the power of multiplying and reproducing itself in the human body, as yeast multiplies itself during the fermentation of beer—is a different and a much more doubtful question. A disorder may be contagious, without this property of reproduction in the animal fluids. The itch is contagious. The itch is produced by a minute parasitic animalcule, the existence of which has, of late years only, been assured to us by the microscope. Suppose that these itch insects could fly, or were capable of being wafted through the air—they would then represent what is conceivable enough of the subtle exciting cause of cholera. Between the two epidemic distempers, influenza and cholera, there were numerous and striking points of similitude and analogy. They have observed the same, or very nearly the same, geographical route. Both, issuing from their cradle in the east, have traversed the northern countries of Europe, till, arriving at its western boundary, they have divided into two great branches; the one proceeding onwards, across the Atlantic, the other turning in a retrograde direction, towards the south and east. The main differences between them have been, that whereas the poison of influenza spared very few of the community, inflicting a disease which, of itself, was seldom fatal—the poison of cholera, on the contrary, smote very few, but with so deadly a stroke that as many sank beneath it, probably, as recovered. Both were *general* disorders, affecting the whole system, but in both the most prominent of the symptoms had reference, in the majority of cases, to the mucous membranes: to those of the air-passages in the influenza; to those of the alimentary passages in the cholera.

Now this strong analogy has been made use of as an argument that the cholera was not contagious. “The influenza (say the objectors) had no contagious properties; therefore it is, *à priori*, likely that the cholera had none.” But I demur to the major proposition. Cullen thought the influenza *was* contagious, and I adverted, in a former lecture, to some facts which favour that belief. Supposing it, however, to be so, the proof of its contagious property must, from the very nature of the case, be extremely difficult. Its visitations are so rapid, widely spread, and multitudinous, that there is no time for its transference from house to house, or from person to person; yet it may nevertheless be transferable. Its inherent rate of locomotion outstrips and precludes the tardier conveyance of the poison by man. Its contagious qualities (granting them to exist) are hidden in its universality, and can seldom be traced but by accident. I therefore esteem this argument from analogy as worthless; and my own creed respecting the cholera is, that it *was* contagious in the limited sense already explained; but that its contagious power was not very great: that a comparatively small part of the population, of this country at least, was susceptible of its operation; and that few were in much danger of suffering from exposure to the physical cause of the disease, except under circumstances of predisposition. At the same time I believe that a great majority of the cases of cholera were not attributable to direct contagion, but to the poison diffused through the atmosphere. There is nothing inconsistent in the supposition that this noxious matter travelled sometimes by its own peculiar powers, sometimes made use of vehicles.

[During the prevalence of the cholera in Philadelphia, in 1832, we closely investigated every fact calculated to throw light upon the question of its contagious or non-contagious character, and for this investigation, our position in the Board of Health and as chief of a large hospital, afforded us ample opportunities—but we were unable to discover the slightest evidence of the disease having been in any one instance communicated from the sick to the well. And yet, there are many curious facts upon record which would seem to give countenance to the idea suggested by Dr. Watson, that the aerial poison productive of epidemic cholera may be conveyed from one spot to another, by persons who are themselves proof against its effects, or who at any rate were unaffected by it. We agree with Dr. Watson that a malarious disease may be portable without its being, therefore, necessarily contagious in the proper acceptation of the term. — C.]

This, I say, is my creed upon the vexed question of contagion. Respecting the special nature of the poison I can only guess; and my guessing, as you may have perceived, takes the same direction as before. I adverted, when speaking of the influenza, to what Sir Henry Holland has called "the hypothesis of insect life as a cause of disease." I shall not repeat the observations I then made; but I would refer you, for such curious thought and information upon the subject, to Sir Henry's very interesting essay. The hypothesis in question squares more readily than any other that I know of, with the ascertained history of the disorder: with its origin, after an unusually wet season, in the low marshy country, and hot atmosphere of Bengal: with its irregular but continuous migrations: with its dying away after a while, and its occasional and partial revivals. But still, remember that we are dealing merely with a *hypothesis*.

Whatever obscurity may overhang the *exciting* causes of the epidemic cholera, we are quite sure that certain circumstances exercised a strong *predisposing* influence upon the human body, to render it more than usually susceptible of the disease. The predisposing causes, as might well be imagined, were such as tended to debilitate the system: and therefore *poverty*, which implies scanty nourishment, and frequently also confinement of several persons to a narrow space, and want of fresh air; poverty, which includes these and other evils, was found to predispose the body to a ready reception of the malady. But to *intemperance*, more than to any other *single* cause, may the proclivity to become affected by this species of cholera be ascribed; and especially to the intemperate and habitual use of distilled spirits. This fact was peculiarly manifested in the selection, by the disease, of its victims in this country; and it has been remarked almost everywhere else.

I have all along spoken of the visitation of epidemic cholera in the past tense, because, for the last eleven or twelve years, we have heard but little of it. Yet we can scarcely venture to hope that the stranger pest has altogether forsaken us, for we have had slight sprinklings of the disease in and near London most summers, I believe, since 1832; but it has never again been extensively prevalent or epidemic. Certainly, it dealt lightly, upon the whole, with our country. It was much more general, and more widely fatal, in France, which it visited subsequently to its arriving here: it was very destructive also in its subsequent course, both westward and towards the south-east.

The epidemic cholera made its attack in two different modes. In one it seized upon the patient suddenly, and without warning. This was comparatively rare. Much more commonly the specific symptoms were preceded, for some little time, even for some days perhaps, by diarrhoea. And this I take to be the most important practical fact that was ascertained during its prevalence among us. When the disease was once fairly formed, medicine had very little power over it; but in the preliminary stage of diarrhoea it was easily manageable. Unfortunately people are inclined (especially those classes of the community among whom the cholera most raged) to regard a loose state of the bowels as salutary: and to make no complaint of it, and to do nothing for it: or, in other cases, they conceive it to proceed from some peccant matter within, which requires to be carried off, and they take purgative medicines to get rid of it. Both of these are serious and often fatal mistakes. Mere neglect of the diarrhoea frequently permitted it to run into well-marked and uncontrollable cholera; and the employment of purgatives hastened or insured that catastrophe. The proper plan of proceeding, I am convinced, was, to arrest the diarrhoea as soon as possible after its commencement, by astringents, aromatics, and opiates. You may object perhaps that the cases that were cured in this way were not cases of cholera at all, and never would have been; but simply ordinary diarrhoea. It is impossible to *prove* the contrary, no doubt; but the presumption is strong that the diarrhoea would, in many, and perhaps in most instances, have run on, if not checked, into the more perilous form of the disease. In many places, when, taught by experience, the authorities established *diarrhoea dispensaries*, to which those attacked by looseness of the bowels were warned and invited to apply, that the looseness might forthwith be corrected; in many such places the cholera, which had before been cutting off the inhabitants by scores, and by hundreds, began instantly to decline in frequency. I venture to advise you, supposing the disease should re-appear, or whenever in the autumn a suspicion arises that this form of cholera is present in the community, not to try, in cases

of diarrhœa, to carry off the presumed offending matter, but to quiet the irritation and to stop the flux as soon as you can.

But when the regular symptoms, peculiar to the severe form of cholera, had set in, medicine, I repeat, had very little influence upon it: and accordingly, as might have been expected, a hundred different cures of the disease were announced, most of them all but infallible. Some persons held that timely bleeding would save the patient: others relied confidently upon mustard emetics. Hot air baths were manufactured and sold to a great extent, to meet the apprehended attack in that manner without delay. Certain practitioners maintained that the disease was to be remedied by introducing into the system a large quantity of neutral salts, which were to liquefy and redden the blood, and to restore the functions of the circulation. But of this practice it was said in a sorry but true jest, that, however it might be with pigs or herrings, *salting* a patient in cholera was not always the same thing as *curing* him. In a great number of the sick the blood was mechanically diluted by pouring warm water, or salt and water, into their veins. Some physicians put their trust in brandy, some in opium, some in cajepout oil, which rose to I know not what price in the market; some again, in calomel alone.

Now, I would not willingly mislead or deceive you on this point, by speaking with a confidence for which I really have no warrant, of the success or propriety of any of these expedients. I believe that each in some cases did good, or *seemed* to do so; but I cannot doubt that some of them did sometimes also do harm. I had not more than six severe cases under my own charge; and I congratulated myself that the mortality among them was not greater than the average mortality. Three died, and three (I will not say were cured, but) recovered. The three that died I was called in to see when the disorder was at its height: in each case it went on with frightful rapidity, in spite of all the means adopted, and proved fatal a few hours afterwards. The three that recovered I saw somewhat earlier, but still not till the specific symptoms were present: one was a girl in the hospital. They all recovered under large and repeated doses of calomel. Yet (as I said before) I do not venture to affirm that the calomel cured them. In the first case which was treated in that way, I merely followed up the plan that had been begun by Dr. Latham, who had visited the patient for me when I was accidentally absent. I found that he had felt better, less sick and less faint, after taking half a drachm of calomel at a dose; and I repeated the same dose many times, for after every dose his pulse rose somewhat, and he appeared to rally. This was the same man whom I mentioned before as having made no urine from the Sunday to the Wednesday: all that time he kept discharging rice-water stools. At last, on the fourth day, he passed a *little* water, and his alvine evacuations became rather more consistent, and began to look *green*: and from that time he gradually got well. Afterwards I treated my hospital patient in the same way, and with the same event. Yet I will not pretend to say that these persons might not have done quite as well if they had been left entirely to themselves.

Some of the expedients recommended had certainly a very marked and immediate effect upon the condition of the patients, especially the injection of warm water into the veins. Many instances of this were related at the time. One I myself saw. The patient was a young man, who was nearly moribund apparently. His pulse had almost, if not quite, disappeared from the wrist; his voice was faint and husky; he was very blue, and his visage was ghastly and cadaverous: in one word, he was in an extreme state of collapse. Out of this he was brought in a few minutes by injecting warm water into one of the veins of his arm. The pulse again became distinct and full; and he sat up, and looked once more like one alive, and spoke in a strong voice. But he soon relapsed; and a repetition of the injection again rallied him, but not so thoroughly: and in the end he sank irretrievably. Dr. Babington told me of a patient whom he saw, speechless, and all but dead, and whose veins were injected. He then recovered so as to sit up, and talk, and even to joke, with the by-standers: but this amendment did not last either. Yet even this temporary recovery might be sometimes of great importance: might allow a dying man to execute a will, for example. And some of the persons thus revived got ultimately well. We had for some time a woman in the Middlesex Hospital acting as a nurse, who had been rescued, when at the verge of death in cholera, by the injection of warm water into her veins.

It was remarked of those who recovered, that some got well rapidly, and at once; while others fell into a state of continued fever, which frequently proved fatal some time after the violent and peculiar symptoms had ceased. Some, after the vomiting and purging and cramps had departed, died comatose; *over-drugged* sometimes, it is to be feared, by opium. The rude discipline to which they were subjected might account for some of the cases of fever. And the process of artificially replenishing the veins was certainly attended with much danger. The injection of *air* with the water—inflammation of the vein from the violence done to it—an over-repletion and distension of the vessels by the liquid—*might*, any one of them, and sometimes, I suppose, *did*, occasion the death of a patient. Never, certainly, was the artillery of medicine more vigorously plied—never were her troops, regular and volunteer, more meritoriously active. To many patients, no doubt, this busy interference made all the difference between life and death. But if the balance could be fairly struck, and the exact truth ascertained, I question whether we should find that the aggregate mortality from cholera, in this country, was any way disturbed by our craft. Excepting always the cases in which preliminary diarrhoea was checked, just as many, though not, perhaps, the very same individuals would, probably, have survived had no medication whatever been practised.

[Soon after the appearance of the cholera in Philadelphia, we were persuaded that had we a remedy capable of arresting the inordinate serous discharge, which in this disease is poured out by the mucous membrane of the alimentary canal, we should very readily succeed in its cure. We were, therefore, induced to try the effects of the acetate of lead, with the remedial powers of which, in a somewhat analogous disease, the cholera of infants, we were familiar. We administered it in pills, combined with opium and camphor, or when the stomach rejected it in this form, in solution with the acetate of morphia, and at the same time, by the rectum, in injections composed of a strong solution with the addition of laudanum. Under this plan of treatment, the discharges were in numerous instances promptly arrested, and the patients recovered, even after approaching collapse was indicated. From our subsequent experience with this plan of treatment, we are convinced, that had the remedy been generally resorted to from the commencement of the epidemic, the mortality of the disease would have been materially reduced. Since 1832 cases of the cholera have occurred almost every year; all that have fallen under our notice were treated by the acetate of lead, and we have lost none.—Dr. Graves subsequently recommended the same remedy, and speaks of its effects in the highest terms.—We usually administer the acetate of lead in the dose of one grain, combined with one of opium and the same quantity of camphor, every hour, or two, or three, according to the violence of the attack. The thirst of the patient was assuaged by small portions of ice held in the mouth and allowed slowly to dissolve—large and frequent draughts of cold water we always found to be injurious.—Cups to the abdomen were frequently employed, and we have reason to believe always with advantage.—From warm bathing, dry heat to the surface, sinapisms, or stimulating pediluvia, or from the internal use of stimulants, we have never seen any good effects result.—C.]

Since the foregoing lecture was written and delivered, the pestilence of cholera has twice revisited this country. I suffer the lecture to remain unaltered, because I still believe it to present, so far as it goes, a faithful outline of that terrible disorder in its intrinsic features, and in its external relations. The larger and the riper experience gathered by a host of competent and keen observers during the prevalence of the last two epidemics, demands however a few additional words of summary and comment.

In their general course and character, the three epidemics of 1831–32, of 1848–49, and of 1853–54 have manifested a strong mutual resemblance. Each had a period of invasion—then a pause—and then again a subsequent fiercer outbreak, determined apparently by atmospheric conditions. All three fell with unequal severity upon different parts of the kingdom; and the parts which suffered the most, and the parts which suffered the least, were, with few exceptions, the same in them all. In each the absolute mortality from cholera was the highest in the months of August and September. More persons died of it in 1849 than in 1832, fewer in 1854 than in

1849. To give you some notion of the desolating power of the disease, I may tell you that during its second visitation there died in England of cholera and diarrhœa upwards of seventy thousand persons. I couple the two advisedly. Each of the three cholera epidemics was preceded and accompanied by diarrhœa, which was unusually fatal as well as unusually frequent. There can be now no doubt that the excess of diarrhœa above the average of common years was due to the exciting cause of cholera; or rather, that most of the cases registered under the head of diarrhœa were really cases of cholera, running a comparatively slow course, and shorn of its more striking symptoms. This fatal choleraic diarrhœa occurred most often at the two extremes of life, while the deaths from fully developed cholera were most numerous in its middle period. It appears from the statistical tables published under the authority of the Registrar-General, that the average duration of fatal diarrhœa was about sixteen days, of summer cholera about five days, of epidemic cholera about two days.

Many converts have been made to the doctrine which I have held from the beginning, that epidemic cholera is *catching*: that it results from a material poison which is portable, capable of being conveyed from place to place, and communicated from person to person—or from inanimate substances to which it clings, such as articles of furniture or clothing. That the morbid matter floats also in the air, and may be wafted about by its currents, is a general and well-founded belief. I think, with Dr. Baly, that when it travels over great distances, as from one country or region to another, it uses the vehicle of human intercourse; but that it may be and often is diffused over smaller spaces, as from one part of a town to another, or from a tainted port to a ship anchored to leeward, by the movements of the atmosphere. The long migrations of the disease are not made rapidly. Its rate of progress never exceeds, and is often slower than, that of modern travelling. Its primary appearance in an island or a kingdom is always at its outer boundary. In our own country, for example, it first planted its foot in a seaport town on the *east* coast, over against the main land where cholera was raging, and whence ships had very recently arrived. The same is true of its two subsequent visitations. On the other hand, the crews of vessels sailing from healthy places remain free from the disease until they have entered an infected port, or held intercourse with an infected shore.

That the poison may thus be carried about is now, I think, beyond dispute. Whether it multiplies itself in the human body as the virus of small-pox does, is still a vexed question. That it must somehow multiply and increase is certain. A theory has been broached by Dr. Snow that the poison is *swallowed* with the food which we eat, or the water which we drink; and that its multiplication takes place in the alimentary canal, whence a new and abundant stock of it is voided. He shows how easily portions of the rice-water excretions, colourless and inodorous as they are, may without our notice come to adhere to our food during its preparation, or its consumption. And the horribly disgusting fact has been made too certain by the unchallengeable disclosures of the microscope, that the water which is supplied by the several water companies for domestic purposes to this great city does habitually contain visible particles of human ordure. Some striking facts have been collected by Dr. Snow, which warrant the presumption that a most fearful outbreak of cholera in Soho was attributable to the water of a certain pump, contaminated from a neighbouring sewer. A remarkable converse fact has been reported by Mr. Lawrence. Bethlem Hospital, and an asylum for children called the House of Occupation, stand near together on an open space of ground between fourteen and sixteen acres in extent, lying in the parish of St. George, Southwark. Being dissatisfied with the filthy water then supplied by the Lambeth Company, the Governors some thirty years ago sank Artesian wells on the premises, and the water thus procured is used exclusively in the two institutions, which number between them about seven hundred residents. There has not been a single case of cholera in the Hospital or in the House of Occupation in any of the three epidemics; although the disease has prevailed extensively in the parish, and in the streets in their immediate vicinity.

The result of an inquiry suggested by the Board of Health into the effects of the consumption of impure water during the last two cholera epidemics, is favourable to Dr. Snow's theory. Mr. Simon reports that "the population drinking dirty water

appears to have suffered $3\frac{1}{2}$ times as much mortality as the population drinking other water."

But granting that the material poison may find its way into the body in company with the food and drink, we must believe that much more commonly it is suspended in the air, and enters with the breath. There are certain conditions of the atmosphere which seem to be almost essential to its activity, and its power to spread. It appears from the extremely interesting report of Mr. Glaisher on this subject, that "the three epidemics were attended with a particular state of atmosphere, characterized by a prevalent mist," (he is speaking of London and its immediate neighbourhood,) "thin in high places, dense in low. During the height of the epidemic in all cases, the reading of the barometer was remarkably high, and the atmosphere thick. In 1849 and 1854 the temperature was above its average, and a total absence of rain, and a stillness of air amounting almost to calm, accompanied the progress of the disease on each occasion. In places near the river night temperatures were high, with small diurnal range. He goes on to enumerate, as characteristic of the atmosphere at these periods, "a dense torpid mist; and air charged with the many impurities arising from the exhalations of the river and adjoining marshes; a deficiency of electricity; and (as shown in 1854) a total absence of ozone, most probably destroyed by the decomposition of the organic matter with which the air in these situations is strongly charged."

The ozone here mentioned is endowed, as I told you formerly, with peculiar purifying properties. It has a high oxidizing power, in virtue of which it unites with, decomposes, and so destroys miasmata, while it is at the same time itself proportionately destroyed. There is no ground for ascribing cholera, as some have done, to the absence of ozone—except in the sense of there not having been a sufficient quantity of it in the atmosphere to counteract all the poisonous miasm which actually produces that disease. The total absence of ozone affords presumptive evidence of the presence of atmospheric impurities.

A remarkable law of *altitude*, that is of elevation above the level of the Thames, has been announced by Dr. Farr as governing the mortality of cholera in this metropolis: and if here, so doubtless, under similar circumstances, elsewhere. "The elevation," he says, "of the soil in London has a more constant relation with the mortality from cholera, than any other known element." The mortality is inversely as the altitude.

This law of altitude—so important and so practically valuable—is but an expression of the result of many concurrent circumstances. The material poison of cholera will be likely to gravitate, as the marsh poison gravitates, with which it has many points of analogy, to the lowest part of the atmosphere; where the high barometrical pressure is the greatest, and vaporous diffusion therefore the least; where unwholesome exhalations from the soil and from the water are the most abundant; where the dispersing and diluting influence of winds is least felt. Indeed the air may be completely stagnant while on the neighbouring heights a brisk breeze is blowing. The lower regions of the atmosphere are the hotter also as well as the moister; and under the agency of a high temperature the organic impurity with which the air is charged runs more readily into decomposition. The inverse law of altitude is therefore an intelligible law. We see also how it may sometimes be disturbed or broken, under exceptional circumstances.

Bear in mind the notorious and lamentable fact, that of this enormous and ever-growing town, the river Thames is made, without metaphor, the common sewer. Foul with the daily and hourly influx of abominable filth, it is offensive to the senses, and a cause of added foulness to the incumbent atmosphere. When we learn from Mr. Glaisher that during the summer months the night temperature of the river is considerably above the minimum temperature of the air, and that its vast area is simmering all night long, and throwing off clouds of noisome and noxious vapour, we need be at no loss to account for the special unhealthiness of those quarters of the town which lie nearest to its banks.

But however unwholesome and pernicious the atmosphere may thus become, it cannot generate cholera, unless the specific exciting poison of that disorder be present also. On the other hand, there is good reason to believe that this poison, although it may strike and destroy individuals here and there, can never create a spreading pes-

tilence, unless it meets with a congenial atmosphere. The foul air lends force and diffusion to the poison, and aids, or causes, its increase. It is the doctrine of some of the soundest physiologists of this country, that the hitherto undiscovered cause of the disease "acts, in its wanderings, after the manner of a *ferment*; that it therefore takes effect only amid congenial circumstances, and that the stuff out of which it brews poison must be air or water abounding with organic impurity. Either in air or in water it seems probable that the infection can grow. The impurity of one commonly implies the impurity of both. But on the whole evidence it seems impossible to doubt that the influences which determine in mass the geographical distribution of cholera in London, belong less to the water than to the air."

This notion of there being two factors requisite for the perfection of the cholera poison, namely, a ferment, or leaven, and a material upon which the ferment operates, was first proposed, I believe, by Dr. Pettenkofer, of Munich.

There is another theory respecting the propagation of cholera to which I must direct your attention, because if it shall turn out to be a true theory, it points to a very plain and easy method of preventing, or checking the extension of any future epidemic. The theory assumes that the cholera poison is an animal poison, and that it is generated in conformity with a law which regulates the development of some other known animal poisons. On a former occasion I spoke of the *cadaveric* poison which is evolved during a particular stage only of the decomposition of dead animal tissues. Now it is held by some eminent pathologists that the characteristic rice-water discharges in cholera, become poisonous after the same rule. At first, for a day or so, they are innocuous. Then, as decomposition proceeds, they become morbid; capable of exciting the specific disease of which they were the product. After a few days more, when decomposition has reached a further stage, the contagious property ceases. Experiments are appealed to in support of this theory. Pieces of filtering paper, soaked in the rice-water fluids and afterwards dried, have been given, re-moistened and mixed with their food, to white mice. Papers steeped in the very recent, and papers steeped in the older discharges, proved alike harmless. But of thirty-four mice that ate papers impregnated with discharges of an intermediate date, thirty were disordered, and twelve died; and the symptoms, and the appearances noticed after death, are said to have been similar to those that are proper to cholera as it is seen in the human subject. The question of the soundness of this doctrine must still, however, be regarded as unsettled.

Whichever of these theories concerning the cause and diffusion of cholera may be the true one—and indeed whether any or none of them be true—they all bear a sufficient amount of likelihood, and are sustained by evidence enough, to render it our imperative duty, in the face of so great a danger, to enforce by our counsel the measures of precaution which they severally suggest. That a strict observance of the requisite precautions would disarm any future return of the pestilence of most of its terrors, and confer upon thousands of individuals the privilege of absolute security, I firmly believe.

And in order to avert so great a prospective peril, from individuals and from the community, no care can be too minute, too early, or too constantly exercised. There is much reason to fear that this comparatively new distemper is already domiciled among us, even as scarlet fever, small-pox, and measles are domiciled. Seventeen years elapsed from its first to its second visitation. The interval between its second and its third was only five: and, what to my mind is still more significant, there has been, since its first arrival, a fearful increase of fatal *diarrhœa* in this country. In 1838, the deaths by *diarrhœa* were 2482; in 1847, they were 11,595; in 1850, 11,468; in 1851, 14,728; and in 1852, 17,617. In this enumeration I have purposely excluded the years and part-years of epidemic cholera; so that the annual mortality from *diarrhœa* has increased sevenfold in fourteen years. It can scarcely be doubted that the milder form of disorder thus largely multiplied, partakes of the choleraic character; or that the embers of the pestilence not yet extinct may easily be roused by favouring circumstances into a fresh conflagration.

Of the circumstances which concur to augment the intensity and to enlarge the operation of the exciting cause of cholera, some are beyond human control; some may be obviated by the efforts of society as a body; some may be got rid of or avoided by each man for himself. We cannot regulate the temperature of the air; nor determine

its barometrical pressure; nor influence, on any large scale, its movements. The removal of decomposing filth, the promotion of ventilation by opening up close and crowded neighbourhoods, the enforcement of effectual drainage, the tapping of gully holes in the streets, the prevention of a perpetual leakage of gas into the subsoil, the constant supply of pure water, the prohibition of intramural sepulture, the emancipation of our noble river from needless pollution, — these are practicable objects, fairly within the scope of legislative action, and imposing very solemn obligations upon our rulers in the State.

But our business lies rather with man in his individual capacity.

Upon the first appearance or threatening of epidemic cholera in this town, I would counsel every one who is not kept within it by necessity or by duty, to fly from the danger; to betake himself, with his household, to the moors of Scotland, to the Welch hills, or to some upland place in one or other of those districts of England which the pestilence has hitherto passed by, or touched but lightly. Which are those districts, may be gathered from the 17th Annual Report of the Registrar General. And there is ample room for choice. People, in these alarms, are apt to hurry to the sea-coast; but that is a mistake. From the same book we learn that a person living in the coast-districts in a cholera season is four times as likely to die of that disease as a person living inland. The east coast, facing the continent, is the worst. The south is better than the west.

In London itself (and what is true of London is true, *mutatis mutandis*, of great towns generally) the more elevated situations are, *cæteris paribus*, the safer, in proportion to their elevation. Wherever he may dwell, every prudent person will look to the efficiency of his drains, and the thorough ventilation of his apartments. During the prevalence of the epidemic, no water should be drunk which is derived from any questionable source; or, if no unblemished source be accessible, all that is used for drinking or for culinary purposes should first be filtered, and afterwards boiled. The artificial waters, soda water or seltzer, when they can be obtained and afforded, are preferable to water of which the purity is doubtful. It is almost superfluous to add that water drawn from a river into which sewers flow, or which is navigated by persons living in boats, should be rejected. Domestic and personal cleanliness, at all times a duty, is now an obligation. No rotting rubbish should be allowed to accumulate in dust-bins. No stench should pass without challenge and correction.

Meanwhile all things which tend to weaken the body, and to dispose it to a ready reception of the disease, should be carefully avoided; intemperance especially — unwholesome food — the use of drastic purgatives.

If, in despite of all precaution, cholera should appear in a house, strict attention to cleanliness becomes even more imperatively necessary. Nurses and others should wash their hands before they eat or handle food. All discharges from the body of the sick person, and all linen soiled with them, should forthwith be immersed in some disinfecting fluid, buried, burned, or otherwise disposed of, before that period of decomposition at which, according to one theory, they become contagious. It has been wisely suggested that the alvine excretions should be received on some worthless material (tow for instance) which might be buried or consumed without delay. A pan containing recently-burned charcoal may rationally be placed in the sick chamber.

Among measures calculated to protect the *community*, by checking the extension of the disease when it is already prevalent, the principal are—

1. House to house visitation by competent inspectors, for the two-fold purpose of enforcing cleanliness and ventilation, and of detecting the malady in its earliest manifestations.
2. The conveyance of the poor who are smitten with the disease to cholera hospitals, or to cholera-wards in the general hospitals of the place.
3. The removal of still healthy poor to houses of refuge, while their tainted dwellings are being disinfected and purified.

The last of these expedients has not hitherto been adopted in London; but it is an excellent expedient, and has doubtless been the means of saving many lives elsewhere, and especially in Scotland. It is stated by Dr. Alison, that of more than 1000 persons in Edinburgh and Glasgow, all of whom were taken from *rooms* in which the disease existed, 40 alone were attacked with cholera, and only 15 died, while 978 escaped

with their lives. In Oxford a similar measure was resorted to in 1849, and not a single case of the disorder occurred among 70 persons to whom shelter was given in these houses.

I can add but little to what I told you formerly respecting the proper treatment of this disorder. Diarrhœa—especially painless, copious, and exhausting diarrhœa, which often is nothing less than incipient cholera—is to be checked at once if that be possible: almost every one has his own drug, and method of proceeding, for that purpose. Sulphuric acid has been highly praised by many. I mention it because it is one of the newest remedies so used, and used with apparent success. In the autumn of 1854 I spent five weeks in a Welch village which (wonderful to relate) did not possess a medical inhabitant. Diarrhœa was exceedingly prevalent there during most of that time. It yielded readily to scruple doses of the *pulvis cretæ compositus cum opio* of the Pharmacopœia. The disorder frequently returned it is true; but that was owing, I believe, to some atmospheric condition which was in continuous operation. The same tendency to recur would probably have shown itself after a cure by any other means. The patient should be kept in bed; which implies quietude, warmth, and (what is very important) the recumbent posture. Most observers agree that in the early periods of an epidemic the prevailing diarrhœa is less easily restrained than during its decline.

In the stage of collapse, I know of no drug upon which any reliance can reasonably be placed. For myself, I should permit the patient to drink as much cold water as he wished for. If he suffered severe pain from cramps, I should seek to give him ease by the cautious use of chloroform: and to these measures I should add full and repeated doses of calomel.

For the fever which in some cases succeeds to the recovery from collapse, and which occurs more rarely without previous collapse, no particular directions can be given. Special attention must always be paid to the kidneys and their functions. These glands become congested in cholera, and the thick blood is loaded and poisoned with undischarged urea. While this unnatural state of things continues, structural mischief is very apt to arise in the kidneys themselves, and in other organs of the body. The remedies are bland diluent drinks, the warm hip-bath, and (perhaps) the removal of a few ounces of blood from the loins by cupping-glasses.

The literature of cholera is endless and perplexing. Dr. Farr's letters in the Reports of the Registrar General; the Report on cholera to the College of Physicians, by Doctors Baly and Gull; Dr. Acland's memoir of the cholera at Oxford; and the several Reports issued on the subject by the General Board of Health, are the best sources of authentic information that I have seen.

[Of the diseases to which children are liable in the middle and southern portions of the United States, few produce a greater amount of mortality annually, than CHOLERA INFANTUM, or the Summer Complaint of children. It is an endemic of all our larger cities, during the season of the greatest heat; attacking children between four and twenty months of age, or at the period of the first dentition. So generally is it confined to this period of life, that an infant's second summer is considered by mothers as one of unusual peril, and should it escape an attack at this period, or pass safely through the disease, it is considered to have a fair chance of surviving the period of infancy.

The first symptom of the disease is usually a profuse diarrhœa, the stools being very fluid, generally of a very light colour, though often of a pale yellow or green; to the diarrhœa is soon added an extreme irritability of the stomach, everything taken into it being rejected immediately, and with violence. The irritability of stomach, in most cases, continues throughout the attack, and in many cases frequent spontaneous vomiting is a prominent symptom.

After the disease has continued for a short time, the discharges from the bowels are ordinarily composed entirely of a perfectly colourless and inodorous fluid, containing often minute mucous flocculi, and are discharged without the least effort. They are occasionally, however, very small in quantity, and squirted, as it were, from the anus. In these cases, there is usually more or less tormina and tenesmus.

Very frequently the vomiting becomes suspended, even at an early period of the attack, while the discharges from the bowels continue, or augment in frequency and

in quantity, the irritability of the intestinal canal being often such, as to cause whatever food or drink is taken to pass off rapidly, without having undergone the slightest change.

The infant becomes quickly affected with extreme languor and prostration, and is rapidly emaciated—being reduced in a few days, often hours, to an extent that would scarcely be credited by those unacquainted with the disease.

The pulse, from the very commencement of the attack, is usually quick, frequent, small, and often tense. The skin is dry and harsh, the head and abdomen are often hot, while the extremities retain their natural temperature, or are even decidedly cold. The tongue is moist, and covered with a white slimy mucus. There is always intense thirst—whatever fluid is taken being almost immediately ejected from the stomach. The child suffers more or less pain in the abdomen, as indicated by its fretfulness, low moaning cries, frequent change of posture, the drawing up of its knees, and its occasional acute screams. The abdomen is sometimes tumid, and generally tender to the touch. Towards evening, there occurs, in most cases, a decided febrile reaction.

In many cases, some degree of delirium, with an injected and wild appearance of the eyes, and a tossing of the head backwards and forwards, is early manifested. When this is the case, we have frequently seen the patient attempt to bite or scratch his attendants.

The disease usually runs a protracted course. The discharges from the bowels continue to be frequent and profuse, but dark-coloured, like dirty water, or the washings of stale meat, and often very offensive. They not unfrequently, however, are small in quantity, and composed entirely of a dark-coloured mucus, mixed with the food and drinks that have been taken. The emaciation of the patient becomes extreme; his eyes are languid, hollow, and glassy; his countenance pale and shrunk; his nose sharp and pointed; and the lips thin, dry and shrivelled. The surface of the body becomes cool and clammy, of a dirty brownish hue, and often covered with petechiæ. The tongue is dark-coloured, smooth and shining, or covered, as well as the parietes of the mouth, with aphthæ. In many cases the child lies constantly in an imperfect doze, with half-closed eyelids, and so insensible to external impressions, that flies will frequently light upon the half-closed eyeballs, without the patient exhibiting the least consciousness of their presence. The abdomen becomes more or less tympanitic, and the hands and feet of a leaden hue, or pallid and oedematous. The fauces, becoming dry, causes a sense of uneasiness, which often induces the patient to thrust his hand deep in the mouth, as if to remove some offending substance.

In many of the protracted cases, an eruption of very minute white vesicles occurs upon the neck and breast. This Dr. Dewees considered to be invariably a fatal symptom; but we have seen many patients recover, even when this eruption has been the most extensive and distinct.

The patient, unless relieved from his suffering by a judicious treatment, becomes daily more and more exhausted, rolls his head about when awake, and utters constantly short, plaintive, scarcely audible cries. He falls at length into a state of complete coma, death being frequently preceded by a convulsive attack. Not unfrequently, at an early period of the disease, the brain becomes affected, and the child dies with all the symptoms of acute meningitis.

Cholera infantum is of very variable duration. In violent attacks, the prostration which suddenly ensues is occasionally so extreme, that the patient is destroyed within the first twenty-four hours. Usually, however, the disease is of many days, or even weeks' continuance, and the patient generally sinks, apparently from a total cessation of the nutrition of the system.

The lesions exhibited by the post-mortem examination of those who have died from cholera infantum, vary according to the period of the disease when death takes place. When the disease has been of short continuance, the mucous membrane of the alimentary canal has been occasionally found of an abnormal paleness, and the liver more or less congested. When the case has been of a more protracted character, increased redness in points or patches, in different parts of the stomach and intestines, is often present. The red points are sometimes very minute and isolated, and spread over a considerable portion of the stomach and duodenum, or over the small intestines

only. They have the appearance, generally, of minute extravasations of blood. In the lower intestines the points occur in clusters, so as to form patches or bands of redness, varying in size, though never of any great extent, and often slightly elevated, from a thickening of the mucous tissue at the parts occupied by them. Occasionally, portions of the mucous membrane are more or less softened—often without the slightest inflammation. In other instances, increased redness of some portion of the intestine exists, with contractions, often extreme, of its calibre.

The mucous follicles of the intestines are very generally enlarged, often in a state of inflammation, and occasionally of ulceration. Dr. Horner describes the appearance of the enlarged follicles, as resembling a sprinkling of white sand upon the surface of the mucous membrane. The intestines are generally empty, or contain merely a small amount of thick tenacious mucus. Drs. Page and Lindsly describe an appearance of dark spots upon the mucous membrane of the stomach, above its pyloric orifice. We have never detected it.

The liver is almost invariably enlarged, and more or less congested; while the gall-bladder is filled with dark-green bile, or a pale and almost colourless fluid. Dr. Page describes the liver as being in some cases large, soft, and spongy; and Dr. Horner, as being usually of a light yellow or mottled colour.

In a few cases, indications of inflammation of the meninges of the brain are present.

The prognosis in cholera infantum will depend very much upon our ability to remove the patient from the influence of the impure, damp, and heated atmosphere by which the disease has been produced and is kept up, as well as upon the period of the attack at which the treatment is commenced. Without this removal, it is scarcely possible to effect, in any case, a permanent cure; while in most cases—in their commencement, at least—little else is required to arrest the disease. Even at a later period, its effects are often strikingly evinced in the rapid improvement of the patient, from almost the very moment the removal takes place. In cases where the disease has continued for many days, and reduced the patient to a state in which a fatal termination would seem inevitable, by removal to the free open air of the country, and an appropriate course of treatment, a very rapid recovery has been often effected.

Cholera infantum is evidently produced by the action of a heated, impure, damp, and stagnant atmosphere, directly upon the skin, and indirectly upon the digestive mucous surface, at an age when the latter is strongly predisposed to disease from the effects of dentition, and from the increased development and activity of the muciparous follicles which takes place at that period.

The dependence of cholera infantum upon a high degree of atmospheric temperature is shown by the fact, that its prevalence is always in proportion to the heat of the summer; the disease increasing and becoming more fatal with the rise of the thermometer, and declining with the first appearance of cool weather in the autumn. That, however, the disease is not produced by heat alone, in its more aggravated forms, is proved by its occurring almost exclusively in the larger and more crowded cities of the Middle and Southern States, and by its especially prevailing, and being most destructive to life, among the children of the poorer classes, inhabiting small, damp, ill-ventilated houses, situated in narrow, confined lanes, courts, and alleys, or in situations abounding with accumulations of filth. When it occurs in the country, which is rarely the case, it is almost exclusively in low, damp, and otherwise unhealthy situations.

The process of dentition is unquestionably a predisposing cause of the disease; while premature weaning and errors in diet act often as exciting causes.

In regard to the treatment of the disease, this is very simple, and generally successful, whenever we are able to remove the patient from the heated, confined, and impure atmosphere by which the disease has been generated, to a situation where he may enjoy the advantages of a cool air and free ventilation.

The infant should be confined to the breast, or, if weaned, to a diet of fresh rennet-whey, with the addition of gum acacia, calves' foot jelly, tapioca, or plain meat broths, with some cool, perfectly bland, and slightly mucilaginous fluid for drink. He should be immersed daily in a bath, warm or tepid, according as the temperature of the skin is deficient or increased.

If the removal of the patient is impracticable, he should be placed in as pure, cool,

and free an atmosphere as possible, and carried frequently abroad in any open and healthy situation in the neighbourhood of his residence, in a carriage, or in the arms — or where his residence is near a large river, he should be taken on the water in a boat. His clothing should be perfectly clean and dry, and sufficient to guard against the influence of sudden changes of temperature, but not so warm as to overheat the patient: fine soft flannel, or soft, coarse muslin, worn next the skin, will be proper in all cases. His sleeping apartment should be, if possible, large, dry, and airy. He should sleep upon a mattress, or on a blanket folded and laid upon the sacking-bottom of the bedstead, or upon the floor of the crib, his body being defended by a light, loose covering.

The gums should be carefully examined, and if they are hot, swollen and inflamed, they should be freely lanced.

When the disease commences as a simple diarrhoea, the warm bath, repeated daily, or even night and morning, and followed by gentle friction over the surface of the body, with a hand or soft dry cloth; cold mucilaginous drinks, and a combination of a sixth of a grain of calomel, about four grains of prepared chalk, and a half a grain of acetate of lead, repeated every three or four hours, will ordinarily arrest it.

To subdue the irritability of the stomach, from a sixth to a fourth of a grain of calomel, rubbed up with a little dry loaf-sugar, and sprinkled upon the tongue, will very generally be found sufficient. When, however, this fails, a few drops of the spirits of turpentine, or a solution of camphor in sulphuric æther, repeated at short intervals, will usually succeed. When the vomiting is violent and frequent, particularly if there is any pain or tenderness of the abdomen, a few leeches to the epigastrium, followed by a light emollient cataplasm or warm fomentations, will be found decidedly beneficial. The effects of fomentations to the abdomen, with a strong decoction of hops, have been spoken of by many practitioners as peculiarly soothing.

A teaspoonful of cold water may be allowed every fifteen or twenty minutes; it is grateful to the patient, and will assist in allaying the gastric irritability.

When the irritability of the stomach is so far quieted as to allow of the remedy being retained, the disordered action of the bowels will in most cases be promptly restrained by a combination of a fourth of a grain of calomel, three grains of prepared chalk, one grain of acetate of lead, and a fourth of a grain of ipecacuanha, given every three hours. Under the use of this prescription, the inordinate discharges will be quickly suspended, and replaced by regular, natural stools. The acetate of lead should be omitted as soon as the watery discharges are arrested, and the calomel, prepared chalk, and ipecacuanha, in the same proportion as above, continued until regular and healthy stools are procured. The use of some one of the light vegetable astringents will complete the cure. The full restoration of the patient to strength will be greatly promoted by a mild unirritating diet, daily exercise in the open air, and the most scrupulous cleanliness of person and clothing.

In cases where much heat of the head, a wild injected state of the eyes, aversion from light, with delirium, or other symptoms of cerebral disease ensue, leeches should be applied to the temples or behind the ears, cold lotions to the scalp, and warm sinapisms, pediluvia, or some stimulating embrocation to the lower extremities. In these cases, blisters behind the ears, kept open by the use of some irritating ointment, will often be found beneficial.

In the chronic stage of cholera infantum, the most efficacious remedies are the warm bath, repeated daily; blisters to the abdomen, kept on until the skin is reddened and then removed, the part being covered with a soft emollient poultice; injections composed of starch and a few drops of laudanum; small doses of Dover's powder at night, with light astringents, as kino, decoction of dewberry-root, or of the geranium maculatum, with change of air, and a diet of boiled milk thickened with rice-flour, or of plain meat broths with the addition of rice. A solution of the tartrate of iron, or of the ammoniated tartrate of iron, twenty grains to the ounce of water, with the addition of a drachm or two of ginger syrup, or the persesquinitrate of iron, may be administered with good effects. In many cases the sulphate of quinia in solution, besides exerting a beneficial influence upon the disordered condition of the bowels, will be found useful in restoring strength to the patient, who is always in a state of extreme prostration.

When the stools are thin, small in quantity, dark-coloured, and highly offensive,

with flatulence, and a tendency to a tympanitic condition of the abdomen, or when frequent griping pains are experienced, the best effects will be derived from the use of turpentine. It may be given in the following mixture:—R. Mucil. g. acaciæ ʒiij.; sacch. alb. pur. ʒij.; spir. æther. nit. ʒiij.; spir. terebinth. ʒij.; magnes. calc. gr. xij.; lavend. spir. comp. ʒij. — M. The dose of which is a teaspoonful three times a day—or oftener, when the child is over two years of age. The addition of ʒiij. of the tincture of kino, and the same quantity of the camphorated tincture of opium, will be proper in cases attended with great irritability of the bowels.

When the discharges are acrid, offensive, and dark-coloured, we have administered with advantage pulverized charcoal, two to eight grains, in combination with two or three grains of powdered rhubarb, a fourth to a half a grain of ipecacuanha, and a grain of extract of hyosciamus every three or four hours.

The utmost attention must be paid to the diet of the patient; he should be confined to meat broths—the juice of roasted meats, with boiled rice—rice milk and tapioca in moderate quantities at a time—with toast or rice water, or rennet-why, with the addition of a portion of gum acacia, for drink.—C.]

LECTURE LXXIII.

Dysentery. Diarrhœa Adiposa. Intestinal Concretions. Worms.

ANOTHER of the morbid fluxes from the alimentary tube, of which I have yet to speak, is *dysentery*.

Its characteristic symptoms are, griping pains in the abdomen, followed by frequent mucous or bloody stools, straining, and tenesmus. In chronic cases pus is sometimes discharged from the bowels. The acute form or stage of the disease is attended with fever.

The difference between dysentery and diarrhœa are obvious enough. Both of them may be accompanied by griping pains: in both the stools are frequent and loose: but in diarrhœa they are fecal; in dysentery there is retention of the natural fæces, or they are expelled from time to time, in small, hard, separate lumps, termed *scybalæ*. Again, straining, and tenesmus, and the excretion of mucus, which is often tinged with blood, form no necessary features in diarrhœa; whereas in dysentery those symptoms are prominent and constant. These nosological distinctions are true and useful, although in our actual intercourse with the sick we do not find them always or strictly observed. Some of the worst forms of dysentery commence with the ordinary symptoms of diarrhœa.

Dysentery consists, essentially, in inflammation of the mucous membrane of the large intestines; yet not, I apprehend, of the whole of that long surface indiscriminately. Observation of the course of the disorder, during life, and of the morbid appearances visible after death, leads to the conclusion that in simple dysentery, marked by tormina and tenesmus, and frequent dejections of sanguinolent mucus, without fecal matter, the inflammation chiefly affects the *rectum* and the *descending colon*. When the earlier portions of the large intestines are involved in the diseased process, the stools at the outset are often composed in great measure of excrement in an unnaturally fluid state, and mingled with blood and slime. We generally speak of these circumstances as constituting *dysenteric diarrhœa*.

Slight and simple dysentery may occur and run its course with very little or no disturbance of the circulation. When it is acute and severe, it is attended with more or less pyrexia. The acute disease may terminate in recovery; or in early death; or in chronic dysentery, which usually, in the end, is fatal.

The wards of our metropolitan hospitals place frequently under our notice severe cases of chronic dysentery in the persons of soldiers and sailors, who bring the disease

home with them from hot climates. With these exceptions, dysentery, now-a-days, is neither a very common nor a very serious disorder in this country. I say now-a-days, for the time was when it raged in London like a plague. The second Dr. Heberden, in his valuable essay, *On the Increase and Decrease of different Diseases*, shows, that in the seventeenth century the number of deaths set down, in the weekly bills of mortality, under the titles of *bloody flux*, and *griping in the guts*, was never less than 1000 annually, and in some years exceeded 4000. For five-and-twenty years together, viz. from 1667 to 1692, they every year amounted to above 2000. During the last century, the number gradually dwindled down to twenty. Dysentery is one of the pests of hot climates. In all tropical regions at certain seasons of the year it is very prevalent and destructive. But it is in fleets and armies, and especially among troops in actual service, that the distemper most displays its terrible power. There is no single malady which is so crippling to an army in the field as this. Sir James M'Grigor, to whom was entrusted the superintendence of the medical department of the army on "the two greatest services on which the military force of this country has, of late years, been employed, namely, that in Waleheren, and that in the Peninsula," calls dysentery "the seourge of armies," and the "most fatal of all" their diseases. In two years and a half, the British army in Spain lost no less than 4717 men by this complaint.

How are these facts to be explained? Wherefore is dysentery, which was so familiar to our ancestors, so happily rare among us? Why does it thus wait upon and afflict the march of armies? Upon what depends its frequency in hot climates? We may expect to obtain some answer to these questions by searching into the *causes* of the disorder.

It has been ascribed to exposure to wet and cold; to the use of unwholesome food; to the agency of malaria; to contagion.

Weather and season have a manifest influence in the production of dysentery. In temperate climates, like our own, it is an autumnal disorder. In tropical countries it is observed to be more common and more severe when rains succeed to a long-continued drought. In respect to this, as to other bowel affections, a high diurnal temperature of the air appears to be the predisposing, and exposure to cold the exciting cause. I stated, on a former occasion, that great vicissitudes of temperature are very frequent and very pernicious, even under the torrid zone. Scorching days are followed by extremely cold nights. The dysentery which arises under these circumstances is apt to run on into the ensuing winter. Soldiers in the field against an enemy are peculiarly obnoxious to the agencies which favour or generate the complaint. Marching, or engaged in actual conflict, during the day; bivouacking at night, often in the open air, and under every variety of weather; ill-provided too often with clothes and bedding; their food scanty, precarious, or of bad quality; seizing the many opportunities which their dreadful trade supplies of license and intemperance; depressed, it may be, by disaster or defeat; we need not wonder either at the prevalence of dysentery among them, or at its untractableness while they remain subject to the same morbid influences. Neither can the causes be warded off from the patient; nor, in general, can the patient be removed from the causes. Yet occasions do arise which show distinctly enough this alleged relation of cause and effect. *Præsens morbum facit—sublata tollit*. Take on the one side, the following facts from Sir John Pringle's book *On the Diseases of the Army*. The men who had fought at Dettingen lay that night on the field of battle, without tents, exposed to a heavy rain. For the next night or two they encamped on better, but still wet ground; and they wanted straw. Nearly half of these troops were soon after affected with dysentery; while three companies which had not been engaged in the battle, nor exposed to rain, nor lain wet, escaped the complaint entirely. Take this converse fact, related by Desgenettes. Four hundred of the French "army of Egypt," reduced to a state of extreme weakness and emaciation by dysentery there contracted, embarked at Alexandria on their return towards France; were carried away, in short, from the alleged causes of their disorder. Nineteen died at the very outset of the voyage; which had, however, so good an effect upon all the rest, that before they reached Malta they were thoroughly convalescent.

The very frequent coincidence or alternation, in some places, of dysentery with intermittent fever, has given rise to the opinion that both these diseases are alike

attributable to the malarious poison. But dysentery prevails where there is no other evidence of the presence of malaria. You may recollect that when we were upon the the subject of ague, I showed you that its repeated paroxysms were attended with extreme and increasing congestion of blood in the internal organs; of which congestion the tumid spleen, the ague-cake, was an effect and a token. Now whatever gorges the splenic vein, gorges its tributary, the inferior mesenteric, which carries the blood from the rectum and the descending colon. Upon such congestion of the mucous membrane, inflammation is readily engrafted; and in this indirect way dysentery may be said to result from the marsh effluvia. Ague is an effect of malaria; and dysentery is, sometimes, a sequela of ague. In precisely the same manner, dysentery is apt to supervene, in hot climates especially, upon *hepatic* congestion and disease. On the other hand, Dr. Budd has taught us how dysentery often leads to a peculiar kind of suppuration in the liver.

That dysentery is, in itself, a *contagious* malady, we have no satisfactory evidence. In its sporadic form, in this country, we never see it spread from person to person. But it is a prominent symptom in some epidemic visitations of typhoid fever, which undoubtedly is contagious. To this I am inclined to attribute the notion, formerly much more common than it now is, that simple dysentery is catching.

The remarkable decline of dysentery in this metropolis, has been contemporary with that of some other severe disorders: and is due to the same combination of causes. For nearly two centuries we have had no *plague* among us. *Agues*, formerly very rife in London, have almost disappeared. *Continued fevers*, which used to break out annually in hot weather, are comparatively unfrequent. I believe that we may trace these great blessings to an event which was regarded by many, at the time, as a national judgment; I mean the great fire that, in 1666, consumed everything between Temple Bar and the Tower. The streets and houses thus destroyed had been filthy in the extreme, close, densely crowded, and consequently most unhealthy. The impurity of the air excited, perhaps, some maladies; and it certainly predisposed those who dwelt in it to various kinds of disease, "the seeds of which (says Dr. Heberden) like those of vegetables, will only spring up and thrive when they fall upon a soil convenient for their growth." To the better construction of the houses and of the streets in the rebuilt city; to the increased means of ventilation; to the general formation of drains and sewers; to the more copious supply of water; and to the more temperate and cleanly habits of the people; we may fairly ascribe our present comparative exemption from dysentery, from ague and continued fever, which are often the parents of dysentery, and from the plague itself. In very many parts of this overgrown place there is still too much room for improvement.

The pyrexia that accompanies dysentery, sometimes begins before the local symptoms declare themselves; more frequently it succeeds their manifestation. Occasionally the fever runs high, the pulse is hard and frequent, the skin hot, the face flushed, and the tongue furred; and the patient complains of headache and thirst. But in this as in other abdominal diseases, the pulse soon becomes small and weak, the strength rapidly declines, and the temperature of the body sinks.

In acute cases the pain is often severe; but it is subject to remissions and exacerbations. It occupies the hypogastrium, or some part of the course of the colon, where there is usually more or less tenderness on pressure. The patient is tormented by a sensation as if there were some excrement ready to be dislodged, goes perpetually to the night-chair, and is irresistibly impelled to strain violently to get rid of the irritation. But the efforts are ineffectual; he discharges but little; and what is voided is either altogether a jelly-like mucus (in which case the complaint has been called the *dysenteria alba*, and the *morbis mucosus*), or more commonly it is mucous and bloody (the *bloody flux* of our old authors), mixed with films, and membranous shreds, and fragments that resemble flesh. In many of the dejections there is no genuine faecal matter at all; or the small indurated balls which I just now mentioned come away occasionally. Frequently the ejected mucus is variegated in colour; green, or black, or reddish, like the washings of meat, and horribly fetid. Sometimes pain and difficulty in making water are added; there is *dysuria*, the irritation of the rectum being reflected upon the bladder through the lower portion of the spinal cord. Sometimes the stomach sympathizes, and nausea and vomiting ensue. With all this local suffering there is a continuance of febrile distress; the patient passes sleepless,

or dreamy and disturbed nights, and is low-spirited and desponding. In the fatal cases the pulse becomes very small and rapid, the features sharpen, and the surface grows cold. Death begins at the heart.

Inspection of the dead body discloses more or less ulceration, chiefly of the large intestine. The glands that lie scattered over its surface are enlarged and prominent, looking somewhat like small-pox pustules, for which indeed they have been mistaken. They probably form the foci of most of the ulcers, which are sometimes narrow and oblong, lying across the gut; sometimes very large and irregular, with here and there islands or ridges of thickened mucous membrane. In the worst cases the whole extent and circumference of the bowel presents, internally, one irregular, confused, and tattered mass of disorganization.

[In the ordinary cases of dysentery, the morbid appearances detected after death are, inflammation with thickening of the mucous membrane of the colon and rectum; occasionally mortification and sloughing of this membrane, but more generally, in protracted cases, deep and extensive ulcerations, in the course of the transverse bands of the colon, or enlargement and ulceration of the follicles of the large intestines. In the more violent forms of the disease, especially those which occur in hot and inter-tropical climates, in addition to the inflammation, ulceration, mortification, or sloughing of the inner coat of the large intestines, there is often morbid vascularity of the mesocolon, mesentery and omentum, with adhesions of the omentum to the adjacent viscera, and of contiguous portions of the intestines to each other. The latter usually happen only when ulcers have perforated nearly all the coats of the bowels. The glands of the mesocolon and mesentery are often enlarged, sometimes inflamed, and more rarely in a state of suppuration; the corresponding portion of the intestine being usually the seat of a deep and extensive ulcer. The omentum occasionally adheres to these diseased glands, forming a band by which a portion of intestine may become strangulated and be the cause of death.]

The ulcerations of the large intestines are commonly most numerous and extensive in the cæcum and upper portion of the colon. The ileo-cæcal valve has, in some cases, been found entirely destroyed by the ulceration; the lower portion of the ileum forming then an intussusception into the cæcum, and becoming there strangulated has caused death. In a few more fortunate instances, the strangulated portion of the ileum sloughs off, after adhesion has taken place between the adjacent parts, so as to maintain the continuity of the canal, when the patient may recover. The right portion of the omentum is not unfrequently found adhering to the cæcum, and this morbid attachment gives rise to symptoms which may be mistaken for hepatic abscess. Sometimes, in the whole course of the colon, we find not more than eight or ten deep ulcerations, with sloughing, thick, abrupt, raised edges, surrounded by an extensive thickened base, into which sinuses and undermining cavities are seen to penetrate. These appearances, Mr. Twining states, (*on the Diseases of Bengal*), have reminded him of the foul ulceration at the centre of a small carbuncle; he has seen several patients die with only six or eight of these ulcers in the colon. The patients had a flushed face, restlessness, and symptoms of continued fever, which were with difficulty controlled by any course of treatment.

The last three or four inches of the ileum are generally studded with superficial ulcerations, and have a rough appearance from the enlarged follicles and glandular bodies; with this exception, we rarely meet with any traces of disease in the small intestines in those who die of dysentery—excepting in those cases in which the dysenteric symptoms occur towards the termination of protracted fevers.

In a few instances the coats of the colon are so much thickened, that, when a transverse section is made, its canal stands open like a thick leathern tube, the interior of the intestine being covered with numerous large ragged ulcers, in the intervals of which the mucous membrane is partly destroyed, and hangs in shreds. In several of these cases Mr. Twining has observed the cæcum, and lower portion of the ascending colon, to be nearly covered with a thick layer of coagulable lymph, deposited beneath the peritoneal coat, and extending a considerable distance along the iliacus muscle; in some instances an unusual amount of fat is found at the same part mixed with the lymph. In other cases, when the disease has been more protracted, the whole of the great intestines are contracted in diameter, resembling a cord, their

mucous coat being at the same time covered with numerous small superficial ulcers. In such cases, also, the internal surface of the cæcum, and of four or five inches of the colon, will now and then be of a livid red colour inclining to brown, having a fleshy appearance, as if from a growth of granulations. Mr. Twining has met with this condition but seldom, but when it has existed, he has found it to extend also to a small part of the sigmoid flexure of the colon. The patients in these cases had become much emaciated, with flat contracted abdomen, dry skin, tongue of a slate colour, glossy and morbidly clean, as if skinned; the stools consisting of an opaque dirty-brown water.

When death takes place after protracted suffering from dysentery, we often find the cellular structure at the root of the mesentery and mesocolon, and across the bodies of the lower lumbar vertebræ, deprived of its usual elasticity and pliability, and to a certain degree indurated; and in many cases entirely devoid of fat. This change is probably the result of a previous inflammation at this part—giving rise to an exudation of coagulable lymph into the interstices of the cellular substance.—[C.]

When submitted to early *treatment*, and when its exciting causes can be averted, or avoided, dysentery is not an intractable disorder. Sir James M'Grigor remarks of the camp dysentery in the Peninsula, that it had two stages, which it was of consequence to note, because they required different and almost opposite modes of treatment: the inflammatory stage, and the stage of ulceration. A plan proposed by Dr. Somers appeared to Sir James so judicious, and proved so successful, in the first attacks of the pure unmixed disease, that he recommended its general adoption in the army. It was this.

First, the patient was freely bled. Immediately afterwards twelve grains of Dover's powder were administered. This dose was repeated three times, at intervals of one hour. Plenty of warm barley-water was at the same time given, and profuse sweating encouraged for six or eight hours. A pill, containing three grains of calomel and one of opium, was directed to be taken every second night; and to be followed on the following mornings by two drachms of Epsom salts, dissolved in a quart of light broth. The venesection was repeated, while the strength and the pulse permitted it, until the stools were free, or nearly free, from blood; and Dover's powder, as a sudorific, was always given after the blood-letting. When the pains were great, and attended with much tenesmus, the warm bath gave instantaneous relief. "This plan being steadily persevered in for a few days, the inflammatory diathesis of the intestinal canal, which had excited symptomatic fever throughout the general system, was found gradually to yield, and to make way for returning health."

If the disease were not cut short by this method, but advanced into the second stage, and became chronic, the most effectual remedies appeared to be laxatives, and opiates, given alternately; and combined with such medicines as promote perspiration. The abdomen should be swathed with flannel, or covered by a warm adhesive plaster. Much benefit may be obtained from the employment of clysters, if there be not too much tenesmus to admit of the introduction of the pipe of the injecting syringe. Warm starch, with laudanum in it—not exceeding in quantity a couple of ounces, lest the irritable bowel should expel it again—will sometimes afford signal relief. Or if the pain and tenesmus are so great that a clyster-pipe cannot be used—or the enema be not retained—a grain or two of solid opium inserted into the rectum, beyond the sphincter ani, will often allay the distress. The food should be farinaceous and simple; and great care must be taken during the convalescence to prevent a return to improper diet, and any fresh exposure to cold.

There is one important point in the treatment of dysentery, concerning which a striking discrepancy of opinion exists, even amongst practitioners who have had large experience of the disease: I allude to the employment of mercury as a remedy. I have no data for settling the question: but the amount of evidence appears to be against its indiscriminate use. It seems (as we might expect) to be powerful both for good and for evil. Sir James M'Grigor has probably hit the distinction which should guide us to prescribe, or to withhold, this drug. It was, he tells us, when the dysentery was complicated with disease or disorder of the *liver*, that mercury proved so highly useful: when along with the dysenteric symptoms there were present a dull pain in the hepatic region, and in the right shoulder, a yellowish brown colour of the

skin, and of the conjunctiva, and uneasiness when the patient lay in any other posture than on the right side. He adds: "In the early stage of the acute and unmixed disease, and before venæsection has been performed, mercury will aggravate the symptoms. In the more advanced stage of the disease, particularly when there is hectic fever, with extensive erosion or ulceration of the intestine, it is invariably found to hurry it on to a fatal termination."

The sporadic dysentery which we chiefly see in this country seldom requires the lancet. Leeches, however, are to be applied, in the track of the colon, wherever there is much tenderness on pressure. A full dose of castor oil may then be given; and after that an opiate. It is the practice of some physicians to prescribe laxatives and opium together; but in this complaint it is better to alternate them. Opium enemata are of service for relieving tenesmus. These remedies will be much assisted by the warm bath; by hot fomentations to the abdomen; and by such means as promote the natural secretions of the skin. If there be any reason to suspect that the portal system is gorged with blood, complete relief to the dysenteric symptoms may often be obtained by the practice which I recommended as proper in *melæna*; viz., the exhibition of five grains of calomel at bed-time, and of a senna draught the next morning, for two or three days in succession. Should the symptoms still drag on, it may be necessary to give mercury, even to the extent of making the gums tender; but it should be introduced gradually. Equal parts of *hydrargyrum cum cretâ* and of *Dover's powder*, constitute a very good combination, either in pill or powder, for such forms of the complaint. But in the milder cases of simple sporadic dysentery there is no occasion, I had almost said there is no excuse, for giving your patient a sore mouth by the lavish employment of mercurial remedies.

[There are many cases of dysentery in which the lancet, or the application of leeches or cups to the abdomen cannot be dispensed with, without endangering ulceration, thickening, or other structural changes in the mucous membrane of the intestines — by which the sufferings of the patient are prolonged and his life endangered. When we consider that the disease consists in fact in an inflammation of the lining membrane of the great intestines, proceeding on, more or less rapidly, to ulceration, and in the more violent cases to gangrene and sloughing, but little doubt can be entertained of the propriety of blood-letting in its early stage in all the more acute cases, occurring in young, robust, and plethoric subjects; even in many of the milder cases, the application of leeches or cups to the abdomen will very generally be attended with marked relief, and will materially shorten the duration of the attack. The more acute forms of the disease can be successfully managed only by the prompt, free, and even repeated use of the lancet, and the application at the same time of leeches upon that portion of the abdomen where pressure causes the most pain; and this system of active depletion must be continued, so long as fever or tenderness of the abdomen continues, more especially if the stools continue to be bloody. The use of the warm bath, in a few hours after the bleeding, and its daily repetition, will always be attended with benefit; or when there is no convenience for the employment of the warm bath, the abdomen may be enveloped with cloths wrung out of warm water, and repeated as they lose their heat, or covered with a light, soft and warm poultice. A large number of cases, if treated at their commencement by bleeding, and the warm bath or fomentations, with a full dose of Dover's powder at night, to ensure repose, will be very readily and speedily cured by these means alone.]

There exists much discrepancy of opinion in regard to the employment of purgatives in dysentery.—Some practitioners insisting that they should be early commenced with, and repeated at short intervals until natural stools are procured. While we cannot perceive any indication that purgatives are calculated to fulfil, which cannot be as effectually met by other less exceptionable remedies, we are convinced that the operation of purgatives cannot fail to increase, in most cases, the irritation of the bowels, and to augment considerably the sufferings of the patient. In cases where ulceration of the intestines is suspected to exist, we consider that purgatives are altogether inadmissible.

Subsequent to bleeding, as well as in those cases in which direct depletion is not demanded, the internal remedy from which we have derived the most advantage, in nearly all the forms of dysentery that have fallen under our notice, is opium in full

doses. We usually administer it, combined with ipecacuanha and nitre, from half a grain to one grain, in conjunction with a third of a grain of ipecacuanha, and three to five grains of nitre, repeated every three hours. After the discharges from the bowels have lost in some measure their slimy, bloody appearance, and though still small, liquid, and frequent, have acquired more of a fecal character, one grain of acetate of lead, with half a grain of opium and one-third of a grain of ipecacuanha, will be found in general quickly to diminish the tormina and tenesmus, and to afford marked and often very prompt relief to the patient.

Blisters are not a remedy from which any advantage can be anticipated until after the more acute symptoms of the disease have been reduced by bleeding — previously they will often do harm, but at this period they will be often serviceable. We have repeatedly observed very great relief to follow their application.

To remove the painful affection of the bladder, with suppression of urine, that so frequently attends violent cases of dysentery, Mr. Twining recommends injections of cold water into the rectum as a remedy the most prompt and certain in its effects. These injections will also be found an excellent remedy for the copious discharges of blood which frequently occur; these discharges will in general, however, be promptly arrested by an injection of ten grains of acetate of lead in six ounces of water.

In cases where the tenesmus is severe during the night, an injection of sixty drops of laudanum in two ounces of cold water will usually remain in the rectum until morning, and promote greatly the comfort of the patient.

The intense sufferings which the patients often experience from the severe tormina and almost constant and distressing tenesmus attendant upon most cases of the disease, are most effectually controlled by full doses of opium. In the more severe forms of dysentery, opium, however, is in general inadmissible until after the violence of the disease has been subdued by direct depletion. It is, when given earlier, apt to mask the more prominent symptoms, and by the calm it thus produces, may lead the physician into a false security as to the condition of his patient while a fatal disorganization is taking place in the intestines. After, however, bleeding, either general or local, or both, according to the violence of the case, has been carried to a proper extent, opium in full doses, combined with ipecacuanha and nitre, by quieting the tormina and tenesmus, will give great relief to the patient and contribute materially to shorten the duration of the most distressing symptoms of the disease. Opiate injections are certainly one of the most prompt and efficacious means we possess of relieving the distressing tenesmus, which often continues to torment the patient after the violence of the attack has been reduced. As an injection, we prefer the solid opium rubbed up with olive oil, flaxseed tea or thin starch. The tenesmus is usually dependent on ulcerations low down in the rectum; and may frequently be relieved by introducing within the anus, three times a day, a portion of the size of a hazelnut of an ointment composed of thirty grains of acetate of lead, mixed with an ounce and a half of fresh lard. When tenesmus remains after the more prominent symptoms of the disease have been removed, an injection of one drachm of acetate of lead dissolved in eight ounces of tepid water was a favourite prescription with Mosely, and in many cases it will afford prompt relief.

The utmost caution should be observed in regard to the nature and amount of the food and drinks allowed to the patient as well during the disease, as in the stage of convalescence. It is all important to keep the colon as nearly as possible empty so long as any degree of inflammation exists. — The practice followed by some practitioners of exhibiting to the patient large quantities, daily, of flaxseed tea and other mucilaginous fluids, under the notion that by so doing we soothe the inflamed intestine, is productive of far more injury than good. Whilst the disease continues the mildest diluents only should be allowed, and these but in moderate portions at a time. Even after convalescence has been fully established, the patient should be restricted to the blandest and most unirritating food, and this in very moderate quantity. Errors in diet, as Mr. Twining very properly remarks, are among the principal causes of a tardy recovery and frequent relapses.

In describing the post-mortem appearances in fatal cases of dysentery, we noticed various morbid conditions of the cæcum as of occasional occurrence; to these Mr. Twining, in his work on the *Diseases of Bengal*, (page 69), directs especial attention. No particular change in the general treatment of the case, however, is de-

manded. All that is necessary is for the practitioner to bear in mind the possibility of the occurrence of more or less violent inflammation of the cæcum, and by the most undeviating perseverance in the employment of the remedies demanded for its removal, especially the local application of leeches, to prevent the disorganization of the intestine, and the death of the patient. "When," remarks Mr. T., "a considerable enlargement of the cæcum takes place, during dysentery, it is usually first noticed about ten or fourteen days after the commencement of the attack. There is not usually so much pain as to make the patient complain, particularly of the part affected; and unless the practitioner habitually examines the abdomen of those he is treating for dysentery, he will be occasionally told of the swelling at a period of the disease when the patient is past recovery: or he will find, upon dissection, such a mass of disease and inflammation, with induration, in the right iliac region, that he will be surprised how it could have escaped his notice during life. Excepting in fat persons, the rounded, doughy, inelastic tumefaction of the cæcum is easily detected by examination with the hand; and, in fact, is often visible on inspection.

The inflammation of the cæcum is to be treated by the daily application of leeches to the right iliac region; the discharge of blood being promoted by warm fomentations or poultices. When by this means the morbid sensibility is removed, and the tumefaction considerably reduced, a blister should be applied and kept open by some stimulating dressing. Mr. Twining recommends as a means of reducing the remaining induration, "a course of Plummer's pill, and extract of colocynth, at night, followed by the compound power of jalap in the morning." "We must remember," he adds, "that no part of the disease can be left unsubdued without hazard to the patient's life."

In chronic dysentery, there is frequent watery purging, attended often with tormina, and very generally with tenesmus, by which the patients are much distressed and soon greatly exhausted. The discharges are mostly of a pale gray colour, often mixed with more or less of a mucous or white slimy substance, and not unfrequently portions of undigested food. They sometimes consist of a copious paste-like brown mass, in a state of fermentation; occasionally, they are frothy, with a whitish or pale grey sediment like a mixture of chalk and beer; in a few very protracted cases, the discharges are very frequent and copious, quite watery, and varying in colour, from a dark-brown to a bright-orange, or from a dirty yellow to a pale straw. They are in some cases inodorous, or nearly so; in others they have a peculiar sickening odour, and in others again they are more or less fetid. Blood is rarely present in the stools, and the patients suffer from fever only in those cases in which there is extensive disease of the mesenteric gland—when they occasionally present a well-marked fever of a hectic character. The abdomen is generally flat, inelastic, and somewhat retracted; occasionally, however, tympanites is a troublesome symptom. The skin is usually dry, shrivelled, and desquamating, and of a dirty brown or sallow hue.

The treatment of chronic dysentery differs but little from that proper in cases of chronic diarrhœa. During the continuance of the disease, and for some period after it has been removed, the patient is to be strictly confined to a mild, unirritating diet, taken in very moderate quantity, and, for drink, to some bland-mucilaginous fluid, as toast or rice water—and even this only in such portions as are necessary to allay his thirst. He should be shielded from the influence of cold and damp, and all sudden atmospherical changes, by flannel next his skin and appropriate clothing, and by a careful attention to the temperature of the chamber he occupies.

Leeches or cups to the abdomen will frequently be found of service—but their use will require judgment, and a close scrutiny of each case in order that any latent or chronic inflammation may be at once detected. Whenever indurations within the abdomen can be felt, and they are attended by morbid sensibility on pressure, or the least degree of febrile excitement, the application of leeches or cups should not be neglected. When the indurations are without sensibility, or after this has been removed, blisters are generally very important remedies. The daily use of the warm bath and warm fomentations to the abdomen assiduously employed, are means from which, in cases of chronic dysentery, the most decided advantage will invariably result. Small doses of ipecacuanha combined with extract of hyosciamus and the blue mass, and repeated every three hours, with a dose of Dover's powder at night, will generally be found to aid very effectually in restoring the capillary circulation to its

healthy state, in quieting the morbid irritability of the mucous membrane of the intestines, in moderating the profuse morbid discharges, and in rendering the stools less frequent and of a more natural character. The balsam of copaiba and turpentine will often be found of equal advantage in many cases of the present affection, as in chronic diarrhœa. In regard to the period proper for the employment of astringents, and the articles of this kind that are best adapted to the disease, the same remarks may be repeated as were made in our note on chronic diarrhœa. — C.]

The fluxes of which I have hitherto spoken have all consisted in an immoderate discharge of some of the usual contents or secretions of the alimentary tube, in an altered and unnatural state. But matters are sometimes voided from the bowels totally unlike any of the healthy discharges. *Adeps* is not an intestinal excretion; yet it is sometimes passed, in great abundance, by stool. Many unquestionable instances of this are on record, both in ancient and in modern literature. I have not seen more than one, and therefore have but little to say upon the subject; yet I must not pass it over altogether. A certain quantity, sometimes it has been a *large* quantity, of oil, of liquid fat, has been poured forth, in a sort of diarrhœa. Sauvages was aware of the disorder, and calls it, in his *Nosology*, *diarrhœa adiposa*. In a paper in the *Medico-Chirurgical Transactions* upon this affection, Dr. Elliotson refers to an example of it described by Tulpus, in which a woman discharged every day, for fourteen months, a considerable quantity of yellow fat, that lay upon the feces like melted butter. When voided into a vessel of water it floated, like oil, upon the surface; and when cold it assumed the consistence and appearance of fat. Like fat, it was very inflammable, and burned with a bright flame. With all this there was no kind of distress, nor any wasting of the body; and the patient was in excellent health sixteen years afterwards. Dr. Elliotson had a case of this kind under his own care. The man had also diabetes and phthisis. The symptoms were precisely the same as those described by Tulpus. Dr. Prout and Dr. Faraday analyzed portions of the adipous matter, and they pronounced it to be genuine fat. Mr. Lloyd, of St. Bartholomew's Hospital, has given us the details of a case in which the evacuation of grease was associated with jaundice. The excretion looked like melted fat, but when cool had the consistence of butter. It swam on the surface of water, melted at a moderate heat, and burned readily. In this instance the head of the pancreas, and the duodenum, were involved in a mass of scirrhus disease. And this is a very curious fact: for Dr. Bright also states that in three different persons, each of whom he had known to pass fat from the bowels during life, and whose bodies he had the opportunity of examining after death, he found scirrhus disease of the pancreas, and fungous disorganization of the duodenum.

The remarkable coincidence, occurring so often, of cancerous disease of the pancreas and duodenum, with these fatty profluvia, is the more memorable, because it falls in with the theory (propounded by Dr. Claude Bernhard, and fortified, as he thinks, by the results of experiments on animals) that one important purpose of the pancreatic fluid is to promote the absorption of fatty matters, by forming with them a permanent emulsion, capable of entering the lacteals. This theory, however, is far from being generally accepted as a proven theory: and even if it be true, it will scarcely account for the *large quantity* of fat which has been excreted in some of the recorded cases.

The single case of which I have had any cognizance is that of a tradesman now living in my neighbourhood, who from October, 1843, to August, 1844, suffered frequent attacks of this kind. First, he had severe pain in the epigastrium and right hypochondrium, with little or no fever, nor acceleration of pulse. Occasionally, when the pain was extreme, it was accompanied by nausea and vomiting. After the pain came jaundice and white stools; and, lastly, a discharge from the bowels of a quantity of white fragments, looking exactly like coarse chewings of walnuts. Sometimes much larger lumps of the same sort were voided. These lumps and fragments were found to be composed of adeps. They floated, many of them at least, and for a while, upon the surface of water. They felt greasy; and burned, like fat, with a flame.

After this series of symptoms the patient would recover perfectly, save that the attacks reduced his strength somewhat. They occurred about once a fortnight, so that he had about a score of them in ten months.

The symptoms resembled those which declare the passage of gall-stones; and upon one occasion two concretions were detected among the fragments of fat. One of these was yellowish; the other black, like a cinder. Once, also, a considerable portion of what seemed membrane came away. My neighbour, Mr. Francis E. Hicks (to whose kindness I am indebted for the opportunity of seeing this patient), is of opinion that a cyst, which secreted the fat, existed in the liver, and discharged its contents periodically; and that the membranous fragment was a part of this cyst.

Projecting a little into the epigastric notch, I could feel what appeared to be the edge of the left lobe of the liver. This spot was slightly tender, and dull under percussion.

I had previously been consulted by the same patient for a chronic and obstinate cough, which after harassing him for three or four years, ceased suddenly, upon the occurrence of the first of these strange seizures. On that occasion he voided at least a quart of the fat. Since August, 1844, he has experienced only two or three slight threatenings of an attack; but lo, his old cough has returned.

Mr. Hicks tells me that a female relative of his own laboured for four or five years under a perpetual dry cough, which was most distressing to herself, and very irksome to the hearers of it. A pint of fatty matter was then passed by stool, and the cough ceased at once, entirely and permanently. This happened more than twenty years ago.

All that we know of the disease seems to amount to this: that it is not a *common* complaint; and that it is not necessarily a *fatal* complaint. Persons who have passed great quantities of fat in that way have lived in good health for many years afterwards. Yet though not *necessarily* fatal, it has frequently been found associated with incurable malignant disease in the duodenum and pancreas. Dr. Prout informs us also that in cases in which a similar oily fluid has been passed through the *urethra*, the *kidneys* have been found in a state of organic malignant disease.

With respect to the treatment in such cases, all the hints I can give you are such as are furnished by the two following facts:—

Mr. Howship, in his book on morbid anatomy, mentions the instance of a lady who was affected with this diarrhoea adiposa, and parted with vast quantities of fat; and who was cured upon the principle of *similia similibus curantur*, for she recovered after swallowing a pint of sweet oil. And Dr. Elliotson, acting on this hint, gave *his* patient, who was labouring at the same time under diabetes, a quarter of a pint of olive oil; and the voiding of fat greatly diminished from that time, and soon ceased entirely.

Whether these were really cures, or whether they were coincidences, is a question which we want larger experience to help us to determine.

When I was speaking of the causes of enteritis, I adverted to the presence of *foreign substances*, as they are called, in the bowels, and to *intestinal concretions*.

There are some points connected with these subjects which I had not then leisure to pursue, but of which you ought not to be ignorant.

Intestinal concretions are very common in some of the lower animals—in horses and oxen especially. Most of you have seen, I dare say, immense intestinal calculi of this kind, and great numbers of them, in the Museum of the College of Surgeons. The old remedies called *bezoars* were of the same nature.

They occur also, these intestinal calculi, in the human entrails, and in various parts of them: chiefly, however, in the cæcum and large intestines, but sometimes in the stomach: indeed, very large ones have occasionally been met with in the latter organ. Bonetus describes one which weighed nine ounces, and was as big as a hen's egg. Generally they are few in number in the same person; one only, perhaps, exists; or there may be two, or three. Yet, as many as thirty have been found together in the stomach in one case: and in another case nine. One of the Monros of Edinburgh (*Monro primus*) detected twelve in the colon of a boy, during life, by the touch. *Monro secundus* took a concretion that weighed four pounds from the colon of a woman. They have been known to measure as much as eight inches in circumference. In the twenty-fourth volume of the *Edinburgh Medical and Surgical Journal* is an account of one long one, or, perhaps, of three that had become united together, weighing twelve ounces. Dr. Turner, of Keith, has published the case of a man,

named Gordon, who, in May, 1841, passed fourteen large intestinal concretions, and recovered completely. At the close however of the year 1843, he began again to suffer, as he had previously suffered, from costiveness alternating with diarrhoea, and from pain and distension of the abdomen. In September, 1847, he one day voided three concretions, each as big as a hen's egg; and on the two following days, fifteen more, varying in size from that of a partridge's egg to that of a filbert. So that in all there came from this patient's bowels thirty-two of these hard bodies.

Now what are these substances, and how do they get there? What is the pathology of the malady? Why, they seem to be formed, in many instances, by the deposit of saline particles, intermixed with animal matter, upon and around some accidental nucleus which has entered the alimentary canal, and there stopped. A gall-stone may form the nucleus: the centre of the calculus has several times been found to consist of pure cholesterine. Those matters over which the gastric juice has no power, and which pass the pylorus unchanged—such as the stones of fruit, husks of grain, many unbroken seeds, portions of bone, and the like. Other of these intestinal concretions are evidently composed of a mass of short fibres, matted, or interwoven together, after the manner of *felt*. These calculi have a somewhat soft and velvety feel, yet are too hard to be much compressed. Sometimes they involve a nucleus, and sometimes they do not. Their composition has been discovered in rather a curious manner. Mr. Clift, who, as you know, had long the main charge of the Hunterian Museum, fancied, after attentively examining some of the specimens there collected, that they might be formed somehow of the beards of oats; and the late Dr. Wollaston, at Mr. Clift's suggestion, I believe, undertook to analyse them somewhat more rigidly; and he found that Mr. Clift's conjecture was well-founded. If you have ever looked closely into the structure of an oat which has been separated from its husk, you may have noticed that one end of it is formed somewhat like a tiny brush; made up of very minute needles or beards. Dr. Wollaston found that these ends were identical in their shape and composition with the fibres of the intestinal concretions.

The accuracy of the result of this analysis is singularly confirmed by the fact that this particular kind of intestinal calculus is almost peculiar to the bowels of Scottish people; among whom, as you know, oats form a very common article of diet, in the shape of oat-meal. The man Gordon, whose case is related by Dr. Turner, lived chiefly upon this meal. Even after his first deliverance, neglecting the advice which had been given him, he recurred to his old habits of diet, and two-thirds at least of his solid food consisted of oat-meal. Sections of the concretions presented the appearance of concentric layers, arranged round a thin shell of phosphate of lime. They were mainly composed of hairs of the *caryopsis*, and fragments of the envelopes of the oat: and they were studded internally with minute crystals.

Concretions of the same species have also been found in the intestines of Lancashire persons; and they also use oat-meal a good deal as food. Mr. Children gives an account of some in the Philosophical Transactions for 1822. The fibres were cemented together by mucus; and the concretions contained albumen also, phosphates of lime and soda, and common salt.

I mentioned formerly the danger which attends the incautious or excessive use of magnesia, whether for stomach complaints or for urinary disorders. When this substance is taken habitually, and when due care is not used to ensure its habitual expulsion from the intestines, it is liable to accumulate and congregate there, especially in the cæcum and colon. Large masses of this kind have been met with, composed almost entirely of carbonate of magnesia.

And the habitual use of any other indigestible substance may have the same ill consequence. The seeds of figs; unbruised mustard seeds, which (as I mentioned before) are taken daily by some persons; the woody knots found in certain pears; all these have been known to form the material of concretions, or of hard injurious masses in the bowels.

Now concretions of this kind come at length to produce symptoms by the pressure and distension they occasion, by the ulceration to which they sometimes give rise, and, above all, by the obstacle they oppose to the passage of the contents of the intestines. They generally cut the patient off by exciting inflammation.

But they may exist for a long time without producing any definite symptoms, or

any serious injury. And when symptoms do arise, or when we ascertain that such concretions have formed, we are often at a loss for a remedy. From the *colon* we may hope at last to dislodge them: by mechanical interference when they are near the outlet: by frequent injections of warm water, or soap and water, whereby they may be softened or broken down, and washed out, when they are beyond the reach of the finger, or of instruments passed into the rectum. In Gordon's case no means were employed till a late period of his disorder. The concretions were voided, with immediate relief from severe suffering, after the daily injection of emollient enemata, and the free use of opiates, which seem to have had the effect of relaxing muscular spasms of the irritated intestine. The patient again regained a state of robust health.

We have an illustration of the patience of the alimentary canal under the presence of these masses, in what often happens when foreign bodies of some magnitude are swallowed, and lodge in the tube.

In one of the earlier volumes of the *Medico-Chirurgical Transactions* you may read the history of a celebrated knife-eater. A sailor, in a drunken bravado, swallowed a clasp-knife. This was followed by no immediate bad consequences, and he used to brag of the feat he had performed. And afterwards, either to satisfy the scruples of those who did not believe his assertions, or else for the sake of rewards which some people were thoughtless or cruel enough to offer, or else to win wagers, he stupidly repeated his folly, till he had swallowed (I think) thirteen knives of various kinds and sizes. They killed him at last, and their remains were found in various parts of the alimentary tract. But he had no serious symptoms for some time.

Mr. Wakefield has given us an account of a culprit, confined in the Cold Bath Fields Prison, who had swallowed seven half-crowns before his incarceration. One day out they all clattered into the pan of his night-chair.

I saw a prisoner myself, some time ago, in the Penitentiary at Milbank, who after some sickness, and tenderness of the belly, voided a half-crown from the rectum. This was in November, 1839. He had swallowed the piece of money two years and a half before — viz., in March, 1837; and, until within a week of his passing it, he had enjoyed excellent health.

Before I proceed to any other of the viscera of the abdomen, I may as well take such notice as the nature and limits of these lectures requires and admit, of the subject of *worms*; in which subject the intestinal canal is more concerned than any other part of the body. It seems a strange, as it is a somewhat humiliating fact, that the human body should furnish food and a habitation for many of the inferior creatures; not only after death, but while it is yet alive. The parasitic animals which thus prey upon man have been much studied from time to time, and especially of late, in their relations to natural history: and some of the facts that have been ascertained respecting them you ought to be acquainted with. But I shall pursue the subject no further in this place than concerns us as pathologists and physicians. Its natural history will, no doubt, be fully taught you by the professor of comparative anatomy.

First, then, it is a notorious fact that numerous parasites do crawl over our surface, burrow beneath our skin, nestle in our entrails, and riot, and propagate their kind, in every corner of our frame: producing oftentimes such molestation and disturbance as require the interference of medicine. Nearly a score of animals that have their dwelling-place in the interior of the human body have been already discovered and described: and scarcely a tissue or an organ but is occasionally profaned by their inroads. Each, also, has its special or its favourite domicile. One species of *strongle* chooses the heart for its place of abode, another inhabits the arteries, a third the kidney. Myriads of minute worms lie coiled up in the voluntary muscles, or in the areolar tissue that connects the fleshy fibres. The *guinea-worm* and the *chigoe* bore through the skin, and reside in the subjacent reticular membrane. *Hydatids* infest various parts of the body, but especially the liver and the brain. A little *fluke*, in general appearance much like a miniature flounder, lives, steeped in gall, in the biliary vessels. If you squeeze from the skin of your nose what is vulgarly called a maggot—the contents, namely, of one of the hair-follicles—it is ten to one that you find in that small sebaceous cylinder, several animalcules, extremely minute, yet ex-

hibiting under the microscope a curious and complicated structure. Even the eye has its living inmates. But it is, I repeat, in the alimentary tube that we are most apt to be plagued with these vermin.

Independently of minute scientific divisions into genera and species, there are some broad lines of distinction between these creatures. Thus, some kinds of worms occupy, as I have said, the interior of our bodies; these are called accordingly *entozoa*: some dwell externally, and are named *ectozoa*; or, more properly perhaps, *epizoa*.

There are five sorts of intestinal worms, sufficiently common to make it likely that you will meet with some or most of them in your future practice. I shall, on that account, direct your attention first of all to them.

1. A frequent tenant of the human intestines is the round worm, so like in shape, size, and general appearance to the common earth-worm. It is from this species, no doubt, that the whole class are called *worms*. This round worm is often erroneously termed a lumbricus. It is a species of *ascaris*, and it has been named by naturalists *ascaris lumbricoides* — the *ascaris* that is like a lumbricus. Oxen, and hogs, are subject to this entozoon.

2. The *ascaris vermicularis*; or the *oxyuris vermicularis*. These animals resemble slender maggots rather than worms. They are often called simply *ascarides*; or, in the vernacular, *thread-worms*; and to the naked eye they look very like bits of white thread.

3. The *tricocephalus dispar*; also a small worm, but longer than the last; its vulgar denomination is accordingly the *long thread-worm*.

4 and 5. Two species of *tænia*; long, flat, articulated animals, resembling pieces of tape. The *tænia solium*, or common tape-worm of this country; and the *tænia lata*, or broad tape-worm. Many of the inferior animals are infested each with its own peculiar species of tape-worm. From their band-like appearance, the *tænia* are also styled *cestoid* worms.

Of all these I proceed to mention a few more particulars.

The *ascaris lumbricoides*, or round worm, is, I say, very like the common earth-worm, and used to be thought identical with it. It runs from five or six inches to about a foot in length, and it is of a reddish brown colour, with a tinge of yellow. The female worm (for they are of both sexes) is much more common than the male, which is smaller also, and may be distinguished by a curved state of its tail, and by the genital organs. Sometimes young ones are met with, about an inch and a half long.

I shall not go into any minute description of the anatomy of these worms. You cannot mistake them, except for earth-worms; and the points of distinction between the two, when known, are easily perceived. The earth-worm, then, is redder than the intestinal worm, and less pointed at its two ends. The mouths of the two differ much. That of the earth-worm is a short longitudinal fissure, or slit, placed on the under surface of its small rounded head. In the *ascaris lumbricoides*, the mouth is situated at the extremity of the worm, is of triangular shape, and is surrounded by three tubercles.

It is curious that similar differences, only reversed, exist in respect to the other aperture of the alimentary canal, the anus. In the earth-worm this is terminal, at the very end of the cylinder: in the *ascaris* it is a transverse slit *near* the extremity, and on the under surface of the animal.

Again, the earth-worm has rows of little projections, like bristles, upon its under surface; feet they may be called, for they appear to serve the purpose of locomotion. In the parasite there is nothing resembling this.

By attending to these plain marks, you may avoid being deceived by impostors, who pretend that they are afflicted with worms, and to prove their case bring you an earth-worm or two in a bottle.

The *habitat* of these worms is in the small intestines. They may, and do, pass upwards into the stomach, or downwards into the large bowel: in either case they are generally soon voided. Sometimes they are vomited up: but they have been known to *creep* into the œsophagus, and thence into the nostrils. Andral states that he saw a case in which a child was strangled by one of these worms, which had turned back

and become entangled in the larynx. They have been found also in the excretory ducts of the liver. This Andral has witnessed; as has also Dr. Baron in this country.

It was formerly thought that these animals were capable of perforating the coats of the intestine: but that opinion is now generally exploded. They do not appear to

possess the means, if they have the inclination, to bore through. What gave rise to this notion was the circumstance of their sometimes passing out of the bowel, through ulcerated or other openings, into the peritoneal sac; or into the vagina or bladder; or out of the body through hernial apertures.

The number of these worms existing at the same time in the same person is very variable. The late Dr. Hooper mentions a girl, eight years old, who voided upwards of 200 in the course of one week. An instance is recorded of a soldier who passed 367 in six days. Another patient got rid of 460 in a fortnight.

Fifty or sixty have been found in the same dead body. They often lie in packets. The corresponding portion of mucous membrane has in some cases been red, in others quite natural. Sometimes two worms are met with; sometimes one only. So that we cannot infer with certainty that because one such worm has been voided, more remain behind; although that is always probable.

This worm is more common in the early periods of life than afterwards.

The other species of ascaris, the *ascaris vermicularis* or thread-worm, resembles the former in some respects, but differs from it remarkably in size. Here also the female is longer and larger than the male; the one being perhaps half an inch in length, the other scarcely two lines, and very slender.

The thread worms live principally in the rectum, and sometimes are collected there in vast numbers; thousands: and they pass out, or are ejected, matted together with mucus in the shape of balls, or entangled in portions of excrement. Sometimes they emerge of their own accord, and crawl about the neighbourhood, getting into the vagina in females, and even into the urethra, and causing intolerable irritation, itching, and distress.

They are seen, when recently expelled, to be very lively; moving their anterior extremity briskly and continually. To this restlessness and activity the animal owes its name, which is derived from the Greek word *ασκαριζειν*, to leap. The Germans call it *springwurm*.

This worm also belongs chiefly to infancy and childhood. It does sometimes infest adults; but generally as the patient grows older the animals cease to trouble him, whether curative means are employed or not. Bremser, however, knew a person eighty years old, who was nearly killed by them.

The third kind of these round worms is the *long* thread-worm; the *tricocephalus dispar*. It is from an inch and a half to two inches in length. One extremity, that to which the head belongs, is extremely fine and small; and then suddenly bulges out a thicker body. The thinner portion is about twice as long as the thicker. Its name is derived from this variation of size. *ῥιξ*, a hair, and *κεφαλη*, the head; the portion to which the head is appended being as fine as a hair. At one time the head was mistaken for the tail, and then the animal was called *tricuris*, from *ῥιξ*, and *ουρα*, the tail. The thicker or body part is rolled up in a spiral form, especially in the male, the female being straighter. This worm is of a white colour, unless tinged by its food. It also affects the large intestine as its place of abode; but the opposite end of that gut, the cæcum, is its favourite spot. It is sometimes met with in great numbers, each attached to the mucous membrane by its head; the body hanging loose.

Although generally overlooked, it is said to be extremely common, and to occur in most bodies. I have seldom seen it; but then I have never hunted for it. It infests the dog, the fox, the monkey, and other mammalia.

This species of entozoon attracted a good deal of attention nearly a century ago; it being then first observed in Germany during the prevalence of an epidemic fever, which was characterized by profuse mucous diarrhœa. Røederer and Wagler have given an excellent account of this disorder, under the title of *morbus mucosus*. It was thought to have been excited by these worms, which were found in abundance in the cæca of the dead. This opinion must have been erroneous, for the animals had been noticed in other places, long before; and they produce, in general, no appreciable inconvenience.

FIG. 118.

Tænia Solium: *a. Head; bb. Lateral orifices.

The two *tæniæ* are more formidable beasts. With a strong general resemblance between them, there are marked particular distinctions.

The *tænia solium*, or common tape-worm, has a minute hemispherical head, which is furnished anteriorly with a double circle of little hooks, and behind these lie four suction disks, whereby it adheres to the inner surface of the intestine. Its body is long and flat, of a whitish colour, composed of many pieces curiously articulated together. The articulated pieces are quadrilateral. Very short, small, and indistinctly marked in the creature's neck, they become gradually larger and square as the distance from its head increases, and at length are longitudinally oblong. So that the worm is narrow and thin at its anterior extremity; one-third or one quarter of a line perhaps in breadth: while at its broadest part it may be from three to six lines wide. The young *tæniæ* seem to be merely wrinkled, but they also are really articulated. The segments of the animal, or the *joints* as they are called, have foramina on their margins, leading to ovaries within. The foramina, which are very conspicuous, are placed alternately on the one side of the animal and on the other: on the right edge of one joint, on the left of that next to it. This arrangement is, however, subject to occasional irregularities. Each joint is let in, as it were, to that immediately in front of it; and the connexion between them is not very firm. It is less firm in proportion as the animal is older, and as we approach its posterior extremity: so that the segments are apt to come away, by stool, separately. They have somewhat the appearance of the seeds of cucumbers or gourds; and the parasites, for that reason, are

sometimes called *cucurbitine* worms. Blumenbach and others have supposed that each articulated piece was a distinct worm; but that is not the case. The head of the animal, and the way in which it grows, and multiplies its kind, forbid this belief.

Within each joint—within at least each of the larger and hinder joints—is contained a complicated male and female apparatus, capable of producing thousands of fertile ova; and the spontaneous separation of these riper segments appears to be a natural provision for disseminating the minute eggs. Meanwhile, as the animal shortens by thus shedding its hindermost joints, some of those which are anterior divide into two by a transverse fissure, which two, after attaining a certain size again divide, and, in this way new joints are formed, and recede gradually from the head. But at a certain distance from the head, the divisions and subdivisions cease, and the whole nutritive power is expended in the development of the organs of generation: and at length ova begin to fill the uteri of the joints. Such is the process (as I learn from Professor Owen's lectures) which has been actually observed by Dr. Eschricht of Copenhagen, in a species of tape-worm (the *Bothriocephalus punctatus*) extremely common in a sea-fish called *Cottus Scorpius*; and it may be presumed that the increase and generation of the human tape-worm proceed in a similar manner.

You will observe that this mode of growth and of multiplication is closely analogous with that of many seed-bearing plants.

Specimens of this worm are preserved, upwards of twenty feet in length. Much exaggeration seems to have existed formerly about its size. It has been said to measure 150, and even 300 feet. In all probability separate portions of several worms have been estimated as forming parts of one and the same worm. There is one case well authenticated (it is cited by Bremser from Robin) in which a tape-worm was found to extend from the pylorus to within seven inches of the anus; adhering firmly to the mucous membrane all the way. The animal has the power of motion. Its movements are felt by the patients, within them. When recently expelled, and placed in tepid water, it may be seen to shorten itself; nay, portions protruding many feet from the anus have been known to draw themselves back again.

This kind of worm is more frequent in adults than in children: yet it is sometimes met with even in the foetus. It has been badly named *ver solitaire*, for it is not always single. It is not only found in company with different worms, but also with others of its own species. Its natural place of abode is the small intestines: but it extends sometimes into the large, and sometimes into the stomach. Vandoverer declares that after an emetic one of his patients vomited forty Dutch ells of the worm, and might have got rid of more "if he had not been afraid of puking out all his guts, and for that reason bit the worm off."

The *tænia lata*, or broad tape-worm, has often been confounded with the *tænia solium*: yet there are striking differences between them: respecting which, for all practical purposes, it is enough to say that the heads (as viewed through a microscope) are very dissimilar, the head of the *tænia lata* having neither a coronet of hooks, nor a circle of suckers; that its joints are shorter and

Tænia lata. *a*. Marks the generative orifices in both. From Owen's lectures.

Tænia solium. Head and joints.

FIG. 120.

FIG. 121.

Tænia lata.

broad, and adhere together in a different manner; and that the pores leading to the oviducts are situate, not on the edge of each joint, but in the centre of its flat

surface. This variety is not so easily broken across as the former; and therefore its segments are less liable to be voided in a separate form. It is probably shorter also than the *tænia solium*. Fifteen feet have been supposed its average length. Marvellous stories, however, are told on this head. Boerhaave declares that he effected the expulsion of one, from the bowels of a Russian, which was 300 ells long.

The geographical distribution of these two species of *tænia* forms a curious part of their history, and throws light upon the long controverted question of their origin. In England, Holland, Germany, and Denmark, the *tænia solium* is common, and the *tænia lata* very rare. In Russia, Poland, and Switzerland, it is just the reverse; the *tænia lata* prevails, the *tænia solium* is seldom seen; while in the French provinces adjoining Switzerland the one species is nearly as frequent as the other.

LECTURE LXXIV.

Entozoa continued. Hydatids. Trichina Spiralis. The Guinea-Worm. Strongylus Gigas. Origin of Entozoa. Question of Spontaneous Generation. General symptoms of the presence of Intestinal Worms. Particular symptoms, and remedies, of the common Round Worm, of Thread-Worms, of Tape-Worms.

At our last meeting I gave a summary description, sufficient, however, for our purposes as medical practitioners, of the five kinds of *vermes* which are the most common parasites of the human intestinal canal. There are yet a few more of these entozoa which are curious and interesting enough to deserve a brief notice.

Hydatids—animals like bags or bladders of water—are of no unfrequent occurrence in several of the internal organs of the body. They are also called *acephalocysts*, headless bags. In size they vary from the bigness of a pea, to that of a swan's egg. They look like, or rather they are, spherical membranous bladders, filled with a thin colourless liquid which holds in solution a large quantity of common salt. Floating in this liquid, and therefore enclosed within what must be considered the primary

FIG. 122.

Acephalocyst.

hydatid, there are usually found smaller ones, of various sizes, sometimes few in number, sometimes in countless multitudes. This seems a consequence of the pecu-

liar mode of propagation of these animals, which is by what is called *gemination*. The wall of the cyst is laminated, and the young hydatids bud from between its layers. In the species that infests the human frame they are born into the cavity of the parent; in some other species they are detached externally. We find, then, a parent bag, containing other smaller bags, which again are pregnant, as it were, with their own offspring, the grand-children of the primary cyst: and so on, somewhat after the manner of a nest of pill-boxes. The primary cyst itself lies in close contact with, but does not adhere to, an external sac, formed apparently by the pressure of the enlarging hydatid upon the texture of the organ in which it is imbedded. These hydatid tumours are more common in the liver than in any other single organ. I lately mentioned the case of a woman, Harriet Baldwin, who died in the Middlesex Hospital, and whose liver contained thousands of these globular bodies. The enlarged gland had completely sealed up, by its pressure, a portion of the inferior cava. They are found also in the lungs, in the spleen, in the mesentery; more seldom in the brain, and in the kidney; and occasionally in other parts of the body. I have called these bags of fluid, *animals*; but perhaps they should rather be regarded as the dwelling-places of much smaller creatures. It was formerly conjectured that they were not parasites nor distinct animals in any sense; but merely certain of those primitive nucleated *cells*, from which the microscope asserts that all the varied tissues of the body are originally formed: cells rendered gigantic and monstrous by some erring or morbid action of the vital forces. Except in size, the cell and the hydatid were held to be alike; alike in shape, alike in the mode of growth and multiplication. But this view of the matter is inconsistent with the result of more recent and more extended observation.

Within several of the transparent hydatids which were taken from the liver of the woman Baldwin, a number of small, opaque, white grains, were visible. These were examined by Mr. Tomes and myself, under the lens of his powerful microscope. They were plainly minute animals: baglike, with an orifice or mouth which, in some instances, protruded a little from the bag, in others was evidently contracted and drawn inwards. Around this orifice was arranged a circlet of small, flat, hook-like rays, somewhat resembling a vandyke collar. Many of these rays, or spines, as they have been called, were detached, and lying loose in the surrounding liquid. Being very ill-informed in this department of natural history, I paid less attention to these creatures than they deserved; fancying indeed that they might be common and well-known, or rather that they were juvenile hydatids. I first became aware of my mistake, through perusing a paper, by Mr. Curling, in the twenty-third volume of the *Medico-Chirurgical Transactions*; where he more minutely describes precisely similar phenomena. The subject has since attracted the attention of many observers, and it appears certain that in almost every hydatid are included more or fewer of these animalcules; which from the spines encircling their heads have been named *echinococci*—hedgehog mites. They have been accounted parasites of the second order, entozoa of an entozoon; but from their general presence it seems more probable that the acephalocysts are mere nests or habitations, formed somehow by, or for, the small indwellers. Professor Owen would have them called *echinococco-cysts*.

Minute in their origin, hydatids may enlarge and multiply till the tumour formed by them attains an enormous size, and at length destroys life by its bulk and pressure; or in other ways which I may have occasion to point out in future. Of course the direct consequences of the pressure will depend much upon the parts occupied by the hydatids. You may readily imagine what kinds of symptoms are likely to ensue when they are lodged within the abdomen; within the less yielding thorax; within the unyielding skull.

We can seldom be sure that hydatids exist within the body, until we see them; nor, if we knew of their presence, could we propose any rational method of cure. It has been fancied that a galvanic current, or an electric shock, passed through the organ containing these creatures, might kill them, and so at least prevent their increase: or that they might be poisoned by alcoholic potations, or by drugs that are

FIG. 123.

Young acephalocysts.

not seriously prejudicial to man, such as mercury, iodine, turpentine. But these, I fear, are mere dreams of our baffled art. They sometimes open a way for themselves to the surface, and escape through an ulcerated outlet: and sometimes they are let out, to the surprise perhaps of the operator, who only knew that he was dealing with an abscess which required puncturing. Mr. Arnott put a lancet into a fluctuating tumour in the epigastrium of one of my patients; very offensive pus issued, with the shrivelled skins of sundry defunct hydatids. The cyst was situated, I believe, in the liver. Although the orifice was slow to heal, the patient ultimately got well. Sometimes the whole colony perishes while yet hid in its dwelling-cave, all the enclosed hydatids losing their vitality, and shrinking up as their fluids are absorbed. It may be that they increase in number and in size till the crowding and pressure prove fatal to them. Their former domicil now becomes their tomb; and effectually precludes any contamination of the fluids of the body, or irritation of surrounding textures, by their remains. This may be deemed a sort of natural cure of such a malady. In the year 1827 I accidentally detected in the liver of a young nobleman a large tumour which, from its size, shape, position, and smoothness, I concluded was produced by a hydatid cyst. He was not even aware of the tumour, and experienced apparently no inconvenience from its presence: it might have been there for years. After some time the tumour became somewhat less prominent. The patient died, of another disease, in 1849; and an old cyst was found containing the dry and withered hulls of numerous extinct hydatids.

There are single cyst-like bodies, with short retractile necks, bearing the generic name of *cysticercus*. One species of this kind, the *cysticercus cellulosæ* (an adjectival epithet agreeing I suppose with *telæ*, understood), inhabits the interfascicular areolar tissue of the muscles. It is rare in the human subject, but frequent in the pig: giving rise to that condition of the muscles which is familiarly known as mealy pork. This is one of the internal parasites with which the organ of vision is liable to be infested. A most remarkable instance occurred a few years ago, in Glasgow. In the eye of a child, who had suffered repeated attacks of ophthalmia, Mr. Logan discovered one day, to his extreme astonishment, a semi-transparent body, about two lines in diameter, floating unattached in the anterior chamber. It seemed almost perfectly spherical, except that from its lower edge there proceeded a slender process, of a white colour, with a slightly bulbous extremity, which appeared to be heavier than the globular part, for it was always turned downwards. This head, or neck, was seen to project or elongate itself from time to time; and occasionally it was drawn up and completely hidden in the cystic portion. When the patient sat still, in a moderate light, the animal covered the two lower thirds of the pupil. "Watching it carefully (says the gentleman who has recorded the case), its cystic portion was seen to become more or less spherical, and then to assume a flattened form; while its head I saw at one moment thrust suddenly down to the bottom of the anterior chamber, and at the next drawn up so completely as to be scarcely visible." The child's head was now turned gently back, and instantly the parasite revolved through the aqueous humour, so that its head fell to the upper edge of the cornea, now the more depending part.

FIG. 124.

FIG. 125.

FIG. 126.

FIG. 125 shows the head in a magnified state: *d*. The proboscis; *e*, *e*, *e*. The suckers.

FIG. 126. — A portion of human muscle with the *cysticercus* inclosed: *a*, *a*. The cyst cut open; *b*, *b*. The parasite; *c*. The muscle.

Upon the child's again leaning forwards, it settled, like a little balloon, in its former position; preventing the patient from seeing objects directly before her.

The animal was carefully watched for three weeks; and no other change was noticed than a slight increase in the bulk of its cystic portion. In six weeks it had evidently grown bigger, the eye became injected, and the iris less free in its movements; and pain ensued. Extraction of the worm was then attempted; but the patient was unruly; the lens was forced out, and the animal ruptured and expelled in shreds: the iris became entangled in the wound of the cornea, and vision in that eye was spoiled.

This cyst-worm has been met with in the brain also, in the heart, and in some other muscular parts. It is generally about half an inch in length.

There is a singular microscopic parasite, the *trichina spiralis*, dwelling in myriads, sometimes, in the muscles of the living human body. It was first described, I believe, by Mr. Hilton, of Guy's Hospital, and afterwards more fully by Professor Owen in 1835. Mr. Wormald, the Demonstrator of Anatomy at St. Bartholomew's Hospital, sent to that gentleman a portion of human muscle, which presented a singular speckled appearance, as if it were mouldy. Mr. Owen found that each speck was a shuttle-shaped cyst, containing a very minute cylindrical worm, coiled up in two, or two and a half spiral turns. The worm measures, when unrolled, no more than $\frac{1}{30}$ th of an inch in length, and $\frac{1}{700}$ th of an inch in diameter; and of course requires, for a satisfactory examination, to be seen through a microscope. The longer axis of the containing cyst lies between, and parallel to, the fibres of the muscle. Fourteen similar instances have since come to Mr. Owen's knowledge.

FIG. 127.

FIG. 128.

FIG. 127.—Cysts of the spiral trichina *in situ*, natural size.

FIG. 128.—Separate cyst, containing the trichina magnified.

FIG. 129.—The animal magnified: a. Head; b. Tail; c. Body.

This is a very strange and puzzling kind of parasite. One would imagine that the presence of innumerable living beings, in or between the muscular fibres, would be likely to give rise to symptoms. We might expect pain, or muscular debility, or embarrassed movements; yet no indication of the presence of these worms seems to have been afforded in those instances in which the condition of the subject in whom they were found was known, during life. The principal points that have hitherto been made out appear to be the following:—

1. The muscles thus beset with parasites are the voluntary muscles: and those which lie superficially are fuller of the worm than the deeper seated. The pectoralis major, latissimus dorsi, and other large flat muscles, usually present them in great abundance. They have been detected in the muscles of the eye; and even in those belonging to the little bones of the ear, of the action of which we are wholly unconscious. They occur also in the diaphragm, in the muscles of the tongue and of the larynx, in those of the soft palate, in the constrictors of the pharynx, in the levator ani, in the external sphincter ani, and in the muscles of the urethra. They have not yet been seen in the muscular tunic of the stomach and intestines, in the detrusor urinae, or in the heart. Mr. Owen makes this interesting remark—that all the muscles infested by the trichina are characterized by the striated appearance of their ul-

timate fasciculi: whereas the muscles of organic life, which the animal does not inhabit, have, with the exception of the heart, smooth fibres, not grouped into fasciculi, but united reticularly.

FIG. 130.

Dracunculus: a.
Head; b. Caudal
extremity.

2. It appears, also, from what has been hitherto observed of these entozoa, that their presence in the body is unconnected with age, sex, or any particular form of disease. They have been concomitant with cancer of the penis; tubercles of the lungs; exhaustion of the vital powers by extensive ulceration of the leg; fever, combined with pulmonary phthisis; aneurism of the aorta; sudden depression or collapse after a comminuted fracture of the humerus; diarrhoea. They have also been met with in the muscles of a man who, while in the apparent enjoyment of robust health, was killed by a fracture of the skull.

The *Filaria Medinensis*—*Dracunculus*—or *Guinea-worm*—has its residence in the subcutaneous areolar tissue. It is a long, slender, round, uniform animal, like a fiddle-string, or a piece of bobbin; as you may see in the specimens before you. Its length varies from five or six inches to twice as many feet. Men's lower limbs, their feet and legs, are the parts most commonly possessed by this worm; but it occurs also in the scrotum, in the parietes of the belly, in the arms, beneath the conjunctiva of the eye, and in almost every superficial situation. It is sometimes solitary; but several may coexist or succeed each other in the same individual; nine or ten perhaps. A Dr. Marrudri, a friend of the celebrated Clot Bey, had suffered from twenty-eight of them in succession.

This entozoon is endemic in the hot intertropical regions; in Asia and Africa; upon the coast of *Guinea*, whence its trivial name. It sometimes abounds after the manner of an epidemic. Sir James M'Grigor tells us that the 86th and the 88th regiments, stationed at Bombay, were much plagued by this pest. The 86th was free from it upon entering the fort, in September, 1799; and so continued till the setting in of the monsoon in 1800. In the course of the monsoon nearly 300 of the men were attacked. The 88th regiment relieved the 86th. No case of Guinea-worm appeared among them for nearly a month after their coming into the barracks at Bombay, in October, 1800. In the latter end of November, they embarked for the Egyptian expedition; and in the course of the voyage, in one ship alone, 199 men out of 360 were crippled and laid up with this loathsome disease. Of 181 instances, of which Sir James M'Grigor gives a tabular account, the feet were the parts affected in 124. This fact is illustrative of the mode in which the animal becomes a parasite. It is believed to be one phase of a very minute worm (about $\frac{1}{60}$ th of an inch long, and exceedingly slender) which, abounding at the bottom of tanks, and on low muddy shores, after the periodical rains, in the regions where the dracunculus is endemic, is there called the *tank-worm*. These tank-worms attach themselves to whatever naked parts of the human body they may chance to come in contact with; and bore their way into and through the skin. Accordingly, the Guinea-worm is frequently met with in the shoulders and backs of water-carriers. In its new habitat the intruder grows immensely, and becomes the nurse or parent of a numerous offspring. In its full grown state it is found to be stuffed internally with a countless progeny of little filariæ. If this stage of parasitic life be essential to its fertility, other animals besides man must, in all probability, furnish the requisite temporary residence.

These worms remain for a considerable time in the areolar tissue without producing inconvenience, and therefore without betraying their presence. Hence they are sometimes brought over to this country. The great navigator, Dampier, had no symptom of a Guinea-worm which he carried about with him, until about half a year after he

left the place in which he contracted it. The period of latency is commensurate with that of growth and incubation, which are probably complete when the young filariæ are ready to disperse and to enter upon their independent life. This period seems to lie between six and twelve months.

The symptoms which do at length arise are the following:—itching of the part affected; a sensation as if there were something creeping under the skin; sometimes a cord-like ridge can be felt in the track of the worm; at length a vesicle, or a pustule, or a little boil forms, from which, when it breaks, the head of the animal protrudes. This process is often attended with fever; and in certain parts of the body the local suffering is considerable: the areolar tissue sloughs; and sometimes dangerous hæmorrhage occurs.

The only treatment which these cases appear to admit of, is the gradual and careful extraction of the worm. Lest that part of it which already protrudes should recede, or be broken, it is gently wound, day by day, round a small stick, or a little roll of adhesive plaster; pains being taken not to pull upon it so much as to risk its being torn asunder. The roll is protected by a bandage. Whenever, by accident, the animal is broken, very serious consequences are said to ensue; violent inflammation of the part, abscesses and sinuses, and high irritative fever. This mischief is ascribed by some to the presence of dead animal matter, by others, of young filariæ, in the sub-cutaneous tissue. The extraction is tedious work. Where, indeed, the areolar tissue is very loose, as in the scrotum, the worm is occasionally drawn out at the first attempt: but the process sometimes occupies weeks; and its average period appears to be not less than ten days. When the course of the animal is quite superficial and obvious, the natives are accustomed to make an incision in the skin, at about the middle point, and to pull the worm through from both ends. When once it is out, the parts presently heal. All other medication (and much has been tried) has been found useless; except, perhaps, the administration of assafetida; and that not as a means of cure, but of prevention. It is said that the Brahmins in India, who are in the constant habit of using this drug, are exempt from attacks of the dracunculus. Cleanliness was also found, in the army, to be a considerable protection. Oiling the uncovered parts of the body has been suggested as a possible defence against the tank-worm.

There is a species of filaria peculiar to the eye; and another to the bronchial glands: but these are extremely rare.

The urinary organs have their parasites also: of which I shall specify but one, and that chiefly on account of its strange lurking-place, and remarkable size. I allude to a species of strongle which sometimes occupies the human kidney, and which is no uncommon tenant of the same organ in various animals; the horse, the bull, the dog, the wolf, the polecat, and the otter. In the human subject its length varies between

FIG. 131.

Strongle of Urinary Bladder.

five inches and a yard, and it is sometimes half an inch in diameter. There is a specimen nearly of that size in the Hunterian Museum. It may well be called the *giant*

strongle, *strongylus gigas*. Fancy a creature as big as a snake coiled up in one's kidney. It gives rise to no distinctive symptoms, although, as you may suppose, it causes much renal distress; hæmaturia, retention of urine, and great suffering in its passage out of the body, either through the natural urinary channels; or by abscess and ulceration through the back.

With respect to some, at least, of the parasitic animals that I have been describing, those I mean which are found shut up in closed chambers, our first feeling is that of wonder how they came there. Into all parts, from which a road is open to the external surface, we can conceive that living creatures may enter, or their eggs be carried. But how can either animals or ova find their way unperceived, into the substance of the liver and of the voluntary muscles, into the eye, into the brain? The whole matter is obscure, yet interesting.

It was the opinion of Linnæus, and of other natural philosophers of his time, that the *intestinal* worms were really terrestrial or aquatic animals which had been accidentally swallowed, either while young and small, or in the antecedent state of ova. It was even pretended that these animals had been recognized and detected out of the body, in stagnant waters. But later inquirers, especially Bremser and Rudolphi, have completely disproved this notion. After dedicating twelve years of his life to the observation and study of entozoa, Bremser was satisfied that no creatures identical in structure with the intestinal worms are ever met with out of the body, except such as have come from the intestines of man, or of some other animal; and conversely, that no terrestrial or aquatic worms are ever found living within the bodies of men or of animals, unless they have been directly and plainly received from without.

But, then, is it not possible that, as Boerhaave supposed, aquatic or terrestrial reptiles, casually entering the body from without, being placed under entirely new and unnatural conditions, may have attained a monstrous growth, and undergone metamorphoses, such as we know that some of the lower animals, by change of circumstances, do undergo; as the tadpole becomes a frog, the maggot a butterfly?

That animals, or the ova of animals, having their proper life out of the human body, may by accident enter it, and having entered may grow, or hatch, is not to be doubted. But that the true intestinal entozoa have ever such an *accidental* origin is rendered very unlikely by the facts that certain species of worms infest certain species of animals only: that in the same animal different species of worms occupy (as we have seen) special parts of the alimentary canal; have each its peculiar habitat: that worms and animals of external origin mostly die as soon as they are received into the digestive organs: while the true intestinal worms perish whenever they are delivered therefrom. Again, the circumstances that these worms not only live but breed within the human bowels, and that they are met with even in the intestines of the unborn fœtus, are very adverse to this theory of an accidental *error loci*.

But to give up the notion of a fortuitous entrance, may not intestinal worms spring from specific germs or ova introduced from without, not casually, but in accordance with a natural law: germs or ova which find in the interior of certain other living bodies the only conditions that admit of their development, the only soil in which they are capable of germinating, the only nest in which they can be hatched? I confess that such has always been my own belief. We have something like this at least in that common affection of horses called the "bots." A species of æstrus or gadfly deposits its eggs upon the animal's hide, where they cause, I presume, some irritation, which induces the horse to lick that part with his tongue. The eggs are thus conveyed into the mouth, whence they reach the stomach. There they are converted into larvæ, and affix themselves to the parietes of the stomach. At length when they are ready to undergo their final metamorphosis, they are detached from the interior of the stomach, pass along with the food and fæces through the intestines, and are ejected from the rectum with the dung.

Why, it is asked, may not similar phenomena take place in the human body? There can be no doubt that we every day swallow, inadvertently, numerous ova, of various kinds. It is supposable enough that sometimes the digestive organs may, and sometimes they may not, have the power of decomposing or expelling these ova.

It is quite certain that what are generally called *spurious* worms may have that mode of origin in the body. Thus Dr. Elliotson states that he had once a patient, an

infant, who discharged from the bowels a dozen live larvæ, or maggots, of the common fly. The child had eaten part of a *high* pheasant some months before. There was, in that case, this instructive circumstance. The infant had been suffering under a chronic cough, but as soon as those larvæ were got rid of, the cough ceased. Dr. Elliotson says that he saw them in the napkin, moving about in the fecal matter, just as they might have done if they had never been in the child's body. The same physician tells us that he has twice known, in two different patients of his, a living caterpillar to be voided from the intestines. One of the patients was a woman who had been in the habit of eating cabbage stalks while she was washing them for the pot. The moth lays its eggs on cabbages, and she no doubt had swallowed some of them, and one had hatched within her. In the ninth volume of Dr. Duncan's *Medical Commentaries* is a precisely similar case. A boy, after a dose or two of calomel and jalap, emitted from the rectum very many caterpillars, all alive, and full of activity. He had been in the habit, when in the garden, of eating young cabbage leaves. Till this habit began he had enjoyed good health. While the animals were within his bowels he suffered severely; had locked jaw; and fell into a state resembling coma. Upon their expulsion he recovered perfectly. Centipedes have in like manner been vomited, and voided from the bowels. But the most wonderful instance of this kind that ever was heard of, is related by Dr. Pickells in the *Transactions of the King and Queen's College of Physicians in Ireland*. A young woman of melancholic disposition and chlorotic appearance, had been in the daily habit, from some superstitious motive, of drinking water mixed with clay taken from the graves of two priests who lived and died in the odour of sanctity. In this way she probably imbibed the ova of the insects which subsequently issued from her body. In the course of about three years and a quarter, she discharged, partly by vomiting, but chiefly *per anum*, upwards of 2000 beetles, and their larvæ, most of them alive. Dr. Pickells counted more than 1300. Larvæ, and pupæ, and perfect insects, all came forth simultaneously. Some of them ran off, as soon as they were vomited, into holes in the floor; and two large winged insects were so lively and vigorous, as immediately to fly away. These strange births were preceded and attended by a complicated and distressing train of symptoms; a gnawing, and sense of something creeping at the pit of the stomach, vomiting of blood, amenorrhœa, hysterical convulsions, headache, retention of urine, and sometimes a degree of mental derangement. She was at length freed from this disgusting malady by large doses of oil of turpentine.

These spurious worms differ from the true intestinal parasites in this—that the human alimentary canal is not their *only*, but their accidental and unusual nidus. Nevertheless, their occasional presence, alive, in that place, adds to the probability that some of the entozoa may be originally ectozoa.

The main difficulty, however, respects those animals which occupy shut cavities within us, or are embedded in our solid organs: and this difficulty forms one avowed ground of the theory of *equivocal generation*: which means the spontaneous production of living creatures, independently of any germ, or egg, or parent. The vulgar suppose that dirt engenders fleas; that maggots result from the putrefaction of flesh; that eels arise of themselves in, and out of, mud; that insects are bred from the dung upon which they congregate and feed. In other words, they infer the spontaneous origin of those creatures, of which they cannot or do not trace the procreation by pre-existing parents: and philosophers and men of science have done the same. They will not believe that which they cannot see. Now this doctrine of equivocal generation shocks, I confess, my mind, and offends my reason. If well founded, it strikes at the root of that great argument of Natural Theology, which deduces the existence of a First Intelligent Cause, from the marks of adaptation, design, and contrivance, so manifest throughout the visible universe. Observe the demand which this doctrine makes upon our faith. In defiance of all experience and analogy with respect to creatures which our finite senses are competent to examine, it calls upon us to believe that living beings of complex and intricate, yet definite and harmonious structure; provided with a digestive apparatus, with instruments of locomotion, with generative organs; of various species; in many instances of separate yet answering sexes; that not one or two of these beings, nor a pair or two, but beings and pairs innumerable, are daily formed by the casual concurrence of "organic molecules." The obscurity that hangs over the origin of some of the entozoa is not indeed the only, nor I think the

chief ground upon which the notion of spontaneous generation rests. You are probably aware that minute animalcules, so minute that most of them cannot be seen without a microscope, soon become abundant in water wherein vegetable or animal matters have been dissolved by infusion. Such animalcules are therefore called *Infusoria*. How do they come there? There are two suppositions open to us. One is, that they are formed by the fortuitous union of organic atoms contained in the infusion. The other is, that they proceed from ova or germs existing in the liquid, or floating always in the atmosphere, and ready to quicken whenever they light upon their proper element. That the ova of animals which are themselves visible only by the aid of a microscope, should be absolutely invisible to us, is not surprising. We may conclude that the latter supposition is the most true, if we can show that when these ova or germs are excluded, all the other conditions of the production of infusoria being present, no animalcules appear. Now Spallanzani long ago found, by careful trials, that no animalcules were discoverable when the access of air to the infusion was completely prevented. But it has been objected to his experiments, that the presence of atmospheric air may be one of the essential conditions which the requisite combination of the organic molecules demands. Air, solar light and heat, and organic matters in solution being given — does animal (or even vegetable) life ever result? That is the question. The experimentum crucis has been made, and has answered “No,” as I learned from one of Professor Owen’s admirable introductory lectures; by whom, I am glad to find, this uncomfortable doctrine of equivocal generation is strongly discountenanced. The experiment to which I refer was conducted by M. Schulze, of Berlin. I will read you his own account of it, as I find it recorded in the *Edinburgh New Philosophical Journal*.

“The difficulty to overcome consisted in the necessity of being assured, first, that at the beginning of the experiment there was no animal or germ capable of development in the infusion; and secondly, that the admitted air contained nothing of the kind. For this purpose I filled a glass flask half full of distilled water, in which I mixed various animal and vegetable substances; I then closed it with a good cork, through which I passed two glass tubes bent at right angles, the whole being airtight. It was next placed in a sand bath, and heated until the water boiled violently, and thus all parts had reached a temperature of 212° . While the watery vapour was escaping by the glass tubes, I fastened at each end an apparatus which chemists employ for collecting carbonic acid; that to the left was filled with concentrated sulphuric acid, and the other with a solution of potash. By means of the boiling heat, everything living, and all germs in the flasks or in the tubes, were destroyed; and all access was cut off by the sulphuric acid on the one side, and by the potash on the other. I placed this easily moved apparatus before my window, where it was exposed to the action of light, and also (as I performed my experiment during the summer) to that of heat. At the same time I placed near it an open vessel, with the same substances that had been introduced into the flask, and also after having subjected them to a boiling temperature. In order now to renew constantly the air within the flask, I sucked with my mouth, several times a day, the open end of the apparatus filled with solution of potash; by which process the air entered my mouth from the flask through the caustic liquid, and the atmospheric air from without entered the flask through the sulphuric acid. The air was, of course, not at all altered in its composition by passing through the sulphuric acid in the flask, but if sufficient time was allowed for the passage, all the portions of living matter, or of matter capable of becoming animated, were taken up by the sulphuric acid and destroyed. From the 28th of May till the beginning of August, I continued uninterruptedly the renewal of the air in the flask, without being able, by the aid of the microscope, to perceive any living animal or vegetable substance, although, during the whole of the time, I made my observations almost daily on the edge of the liquid: and when at last I separated the different parts of the apparatus, I could not find in the whole liquid the slightest trace of infusoria, of confervæ, or of mould. But all three presented themselves in great abundance a few days after I had left the flask standing open. The vessel which I placed near the apparatus contained, on the following day, vibriones and monads, to which were soon added larger polygastric infusoria, and afterwards rotatoriaæ.”

This experiment confirms the belief which various other facts had suggested—that

the different kinds of entozoa are none of them parentless animals, and that they somehow find their way into the body they inhabit, from without. The lowest of the infusoria are of fixed and determinate species; and Ehrenberg states that even the minutest monads possess a complicated organization. It may be asked, concerning both them and the entozoa, why, if they ever arise spontaneously, should they be furnished with a generative apparatus? Again, some of the entozoa abound in certain places, and strangers coming to those places contract them there. The dracunculus was thought by the soldiers in India to be communicable from person to person, as the itch insect, and the chigoe, to both of which it has some analogy, certainly are. The infant filaria probably creeps in through the skin without causing any noticeable pain. Even that monster among the entozoa, the tape-worm, invades the bodies of those persons who visit the countries to which it belongs. I told you before that, when tape-worm occurs in Germany, it is always the *tænia solium*; when in Switzerland, almost always the *tænia lata*. Now the celebrated Soemmering was afflicted with one of these beasts; and he was by birth a German: yet the worm that he voided was of the foreign species, the *tænia lata*. He had resided, however, for some time in Switzerland: and there, no doubt, he somehow picked up the ovum, or the larva, of the parasitic animal. Mr. Abernethy once told me the following curious story:—A shepherd had to drive a flock of healthy sheep to a distant part of the country. The journey occupied two or three days. On the road one of the animals broke its leg, and was carried the rest of the way on horseback. All the flock, except this hurt individual, were turned for one night into a marshy pasture. The broken limb was set, and the patient got well; and was the only one of the whole flock that did not subsequently become affected with the rot; the only one that escaped having flukes in its liver. Is it not almost certain that the germs of these parasites were swallowed with the herbage cropped by the sheep in the damp meadow? Professor Owen suggests that “the young flukes may pass instinctively from the duodenum through the ductus choledochus to the gall-bladder.” The germs of the entozoa which dwell in closed chambers, and within the solid viscera of the body, are probably carried thither by the blood.

The wonderful tenacity of life possessed by some (at least) of these minute creatures, increases the chance of their reaching at last their appropriate habitat, and adds proportionally to the presumption against their spontaneous origin. Spallanzani kept certain infusorial animalcules four years in a state of complete desiccation and apparent death; but they presently recovered life and motion upon being then moistened. He dried and moistened alternately the same animalcules twelve times, with similar results; except that the number of revivers was each time less and less, and after the sixteenth moistening there was no resurrection. The *Vibrio Tritici* (a minute worm which is a parasite of wheat) having been dried by Mr. Bauer, resumed its activity, when remoistened, after the lapse of from four to seven years. Another small parasitic worm has been seen to exhibit strong contortions—evident vital movements—after having been subjected for above an hour, together with the cod-fish which it inhabited, to the temperature of boiling water. On the other hand it is stated by Rudolfi, that entozoa which infest the herrings annually sent to Berlin, hard frozen and packed in ice, do, when thawed, manifest unequivocal signs of restored vitality. “If,” (says Professor Owen, from whom I take these facts,) “the fully developed and mature entozoa can resist such powerful extraneous causes of destruction, how much more must the ova possess the faculty of enduring such without losing their latent life.”

The difficulty belonging to this subject was materially lessened by the curious modern discovery, first announced by M. Steenstrup, of *alternating generations*. “The young of most of the entozoa undergo metamorphoses.” Certain entozoa, the parasites of certain animals, have been ascertained to present merely a transition state of other entozoa, the parasites of certain other animals. In the last edition of his Lectures, Professor Owen stated the probability that the whole of the *cystic* family of entozoa were nothing else than the larvæ of the whole *cestoid* family: a doctrine which may now be said to be fully established. The doctrine was suggested by definite resemblances and relations subsisting between the two sets of entozoa on the one hand, and between the two kinds of animals respectively infested by them on the other. The first, or lower sort of these entozoa, are so far imperfect, that they are sex

less, have no generative organs. The second, or higher, possess, as I have shown you, an apparatus for most abundant reproduction. Parts of the first have a close rudimental likeness to corresponding parts of the second: their heads, especially, exhibit a striking conformity of structure. This is the sort of relation which is observed between the *entozoa*. That which exists between the two *infested animals*, is the relation of natural prey, and devourer. To take an example by way of illustration. The common domestic mouse and rat are subject to a species of cyst-worm, the *cysticercus fasciolaris*. The cat, which preys on these animals, is subject to a species of tape-worm, the *tænia crassicolis*. Now this *tænia*, Professor Owen informs us, is remarkable, among *tænia*, for the disproportionate size of its head, its short and thick neck, the position of its four suetorial disks, and the shape and number of the hooklets of its proboscis: and all these peculiarities are repeated in the *cysticercus* of the mouse and rat, which cyst-worm he regarded accordingly as the larval form of the tape-worm of the cat. Nor is this a solitary instance. "All the *cysticerci* manifest their affinity with the *cæstoidea* by the organization of their heads." I may add that their necks are divided into segments resembling the joints of the *tæniæ*. They seem, in fact, part hydatid, part tape-worm.

This doctrine has since been confirmed by the experimental researches of several eminent German naturalists. Küchenmeister was the first, I believe, to feed dogs and cats upon flesh that contained living cyst-worms. After a while he found corresponding tape-worms in the intestines of those dogs and cats. But he was not content with practising upon these *corpora vilia*. He conceived and executed the horrid and revolting project of sowing (as it were) cyst-worms in the human bowels. He contrived to mix *cysticerci*, collected from pigs and rabbits, with the food of a criminal under sentence of death for murder, passing them off as grains of rice in warm rice soup, as bits of paste in vermicelli gravy, and as small lumps of fat in black-puddings. These were swallowed by the unconscious and wretched man at various periods from seventy-two to twelve hours before his decapitation. Forty-eight hours after it, ten young tape-worms were seen attached by their hooks and suckers to his small intestines.

Similar experiments upon the lower animals were carefully repeated, with similar results, by Professor Siebold. The transformation of the imperfect cyst or bladder-worm into the perfect tape-worm was thus satisfactorily demonstrated. To elench the proof, the converse experiment has since been made. Joints full of ripe ova, from the tape-worm of a dog, were given with their food, by M. Haubner, of Dresden, to certain lambs. In about a fortnight all these lambs (and no others in that flock) became affected with what is called "the staggers;" and when they were killed, at different intervals, cyst-worms, in various stages of growth, were discovered in their brains, and in other parts of their bodies. Again, mice were induced by Professor Leuekart, of Giessen, to eat mature joints of the *tænia crassicolis* of the cat; and the livers of those mice were found thereafter to be studded with the *cysticercus fasciolaris*. Swine also, fed with the eggs of the *tænia solium*, and killed some weeks afterwards, were occupied throughout their whole bodies with the *cysticercus cellulosæ*.

Whether the several cyst and tape-worms are distinct in species, or mere varieties determined by the species of animal which they infest and feed on, has not, so far as I am aware, been ascertained. It is however believed that the *cysticercus tenuicollis*, nursed in the ox and other ruminant animals, is transfigured and completed into the *tænia serrata* of the dog; and that the *cysticercus pisiformis* of the rabbit and hare, becomes in the fox, which eats them, the *tænia crassiceps*. Reasons were suggested, in 1852, by Dr. Nelson, for thinking, what can now be scarcely doubted, that the *cysticercus cellulosæ*, hatched in the bodies of measly pigs, is matured in the human body into the *tænia solium*: and if the kind of animal in which the ultimate metamorphosis takes place, determines the specific form of the resulting *tænia*, that of man may sometimes be derived from *cysticerci* which haunt the bodies of sheep and oxen. Pork is eaten raw by many farm-labourers in this country, and with it the cystic larva of the *tænia solium* must be often transplanted into their bowels. The taste for raw or half-cooked meat is not uncommon. It is a reasonable conjecture that the *tænia lata*, which is endemic on the shores at the head of the Gulf of Bothnia, and frequent in the neighbourhood of the Swiss lakes, may be the adult

form of a cystic entozoon from some marine, or fresh-water animal. Professor Siebold believes that certain minute worms which infest a species of *slug*, are the produce of ova from the *tænia* of some bird. The ova are voided with the excrement, and the creatures hatched from them may be presumed to creep upon the body of the first slug that may crawl near them: and then, if they have the additional good luck to be swallowed, with the slug, by the proper bird, they regain a fitting nidus for their further and perfect development. Our red grouse, a bird peculiar, I believe, to the British Islands, are very subject to tape-worms. In some years thousands of them die of this distemper. If any of you can succeed in tracing the birth and nursery habits of these destructive parasites, so as to prevent their final development in the grouse, you will secure the praise and thanks of a great number of English sportsmen. We may take for granted that the little echino-coccus is the cystic stage of some tape-worm; but to what animal the tape-worm specially belongs, is as yet an unsolved mystery.

Of the innumerable eggs produced by the human and by other tape-worms, very few can ever reach the fitting nidus for their first hatching into the cystic state, and fewer still the remoter place of their final mutation into perfect *tæniæ*. Professor Owen remarks that many of these little ova, in great cities especially, must eventually find their way into streams of water, for whose minute inhabitants — or for terrestrial creatures under other circumstances — they probably furnish food: being thus analogous to the seeds of the fruitful *cereal*ia, which “minister far less to the perpetuation of their own species, than to the sustenance of man.”

After all, it is a mortifying rebuke to human vanity, that for the birth, the nurture, and the support of a repulsive, a noxious, and (so far as our finite faculties can perceive) a useless parasitic worm, the subservience should be required of two other creatures of higher grade, and (as we speak) of nobler dignity in the scale of life; one of which is no less a being than that “paragon of animals,” Man.

Upon the whole, we may reject the hypothesis of equivocal generation, and fall back upon the Harveian axiom, taken in its most extended sense, of *omne vivum ex ovo*. If I have digressed somewhat in order to set before you the grounds of my own belief in this matter, the interest and importance of the subject must be my excuse.

What I have further to say will relate exclusively to the intestinal worms of the human body: their predisposing causes; the symptoms they occasion; and the methods of getting rid of them.

Of predisposing causes there is little to be said. I know of none except the endemic or the accidental prevalence of the outward germs of these worms, and the personal habits of those who are liable to their intrusions. The *tænia solium* has been observed to be common among pork-eating communities; the cyst-worm from which it is bred being, as I have already stated, a very frequent parasite of the omnivorous pig. By the same rule, it is said to be very rare among Jews. Wherever raw meat forms a part of the food of the people, as in Abyssinia, there we find the tape-worm prevalent. Even in this country the taste for raw meat appears to be less singular than one might have supposed. Dr. Willshire has lately published several instances, as Dr. Crichton had previously published one, of the coincidence, in the same person, of tape-worm, with the practice of eating raw or under-done flesh.

It more concerns us to inquire into the general symptoms, through which the existence of worms in the alimentary canal may be ascertained, or suspected.

Those symptoms are very multifarious; and, for the most part, very equivocal. I know of none that can be reckoned certain or pathognomonic, except the actual appearance of one or more of the animals, or of portions of them, in the excrements of the body. Yet that they do give rise to a variety of morbid phenomena — which morbid phenomena are, however, liable to be produced by other causes also — there can be no question.

The most common of these are well known to all nurses and old women; such as colicky pains, and swelling of the belly; picking of the nose, in consequence of itching and irritation there; itching of the fundament; a foul breath; grinding of the teeth during sleep; a variable and capricious appetite, sometimes voracious and insatiable, sometimes none at all; and irregular bowels.

Worms now and then occasion strange, and even severe *nervous* symptoms, explainable upon the principle of the reflex office of the spinal cord. We conclude that the symptoms are owing to worms in such cases, because they cease when the creatures are got rid of. Some examples of this I have already noticed. Thus Dr. Elliotson's infant patient lost a chronic cough upon the expulsion of the live larvæ of the common fly. Bremser gives a very similar case. A child of eleven, afflicted with tænia, had a troublesome dry cough. It was observed that the cough was suspended for two months, just after a very large portion of the worm had been brought away by anthelmintic medicines. This kind of coincidence happened, not once only, but three or four times; and at length, when the whole of the worm had come away, the cough was permanently cured. You may read an instructive instance of the same kind, in Dr. Graves' Fortieth Clinical Lecture. I mentioned, some time ago, the frequent association of intestinal worms with epilepsy, which is then of the eccentric form: and I stated that a certain nobleman voided some kind of worm (a tape-worm, I think) from his bowels, and was thenceforward free from epileptic fits, under which he had long laboured. A curious circumstance, illustrating the fact that irritation of the mucous membrane of the alimentary tube may affect distant parts, is quoted by Dr. Joy from Albinus. A soldier received a wound, which led to the formation of an unnatural anus, in front of the abdomen, and in the track of the colon. Through this opening the mucous membrane of the bowel sometimes protruded; and whenever it was out, and exposed to the contact of cool air, the patient began to cough; and continued to do so till the mucous surface was warm again. Partial palsy, amaurosis, aphonia, and other nervous symptoms, occasionally depend upon the presence of worms in the intestines.

[Dr. Schleifer, in the Austrian Weekly Journal of Medicine, relates the case of a child, nine years of age, who became dumb, after suffering in early life from cutaneous eruptions, engorgement of the glands, &c. The loss of hearing was attributed chiefly to a fall, and treated accordingly. The child became emaciated, pale, with a dark leaden appearance of the contour of the eyes. The tongue was white and loaded, the breath offensive, and the abdomen tumid and hard. The muscles of the face were in constant motion, and the patient moaned incessantly. Dr. S. suspected the presence of worms, and treated the patient accordingly. In three weeks, eighty-seven lumbrici were discharged, and, during five weeks, immense quantities of ascarides. At the end of the sixth week, the child had recovered his hearing and speech.

In the Journal of Medicine and Surgery of Paris, for April, 1844, a case is quoted, from the Gazette Médicales de Dijon, of a young man, nineteen years of age, who was attacked with all the symptoms of acute pleurisy: chill, followed by fever; severe pain in the left side; difficult, jerking respiration; paroxysms of dry cough, which occasioned the patient to scream out, &c.; all of which symptoms promptly disappeared after the discharge of seventy-five lumbrici.—C.]

But let us examine into the symptoms which are more or less proper to particular species of intestinal entozoa; and into the treatment which they severally require.

A variety of symptoms are ascribed to the *ascaris lumbricoides*. Dr. Baillie says that the most characteristic are a tumid belly, emaciated extremities, offensive breath, and a deranged appetite. To these may be added colicky pains of the abdomen. When these animals get out of the small intestines, and ascend into the stomach or œsophagus, they may occasion pain, nausea, vomiting, even convulsions. They have caused death, as I mentioned before, by crawling into the biliary ducts, and into the chink of the glottis. Sometimes, on the other hand, they emerge, unexpectedly, from persons who had received no previous notice of their presence within.

This, the commonest parasitic tenant of the human bowels, is also a troublesome one to eject. A great variety of anthelmintics have been cried up as successful against it, but brisk purgatives and bitter medicines in the intervals, have the best evidence in their favour. These animals seem not to like steel; and my own plan of assailing them is that of purging the patient from time to time by calomel and jalap, and administering three times a day, some preparation of iron; the sulphate, or the muriated tincture. I believe that most of the patent worm remedies consist of mercury, jalap, and scammony, given in strong doses. The fœtid drugs, assafoetida, galbanum, valerian, are often used. Cowhage also, the *dolichos pruriens*, which is

supposed to tease the skin of the parasite no less than that of the human worm; and tin-filings, which are thought to bruise or lacerate the offenders, are favourite medicines with some persons. I have never tried them. The oil of turpentine I have not found so effectual in expelling this species of ascaris, as I shall presently show you that it is against the tape-worm. Croton oil has been much commended, either given by the mouth or rubbed upon the abdomen. Common salt, coloured by cochineal, and exhibited every morning in half-drachm doses, was found by Dr. Rush to be very successful.

The symptoms produced by the *ascaris vermicularis* are itching and irritation about the anus, especially in the evening, and at night. The annoyance is aggravated by the warmth of the bed, and by whatever overheats the body. I would refer you to a paper by Dr. Heberden on this subject, in the first volume of the *Medical Transactions*. The case he describes is the more valuable, as it was related to him by a physician who was all his life plagued by these thread-worms. Generally, however, they infest children; and become fewer, and at length disappear, as childhood passes into youth. When they do accompany life through its several stages, although they are a source of great worry and suffering, they do not appear to shorten the duration of the patient's existence.

To introduce at one end of a twisted tube, several yards long, substances which are intended to act upon animals that live quite at its other end, would be a very round-about course. Whether a purgative effect, or a specific destructive effect, be the object, enemata are preferable to medicines given by the mouth. Bitters offend and destroy these little worms. I have relieved many patients from their tormentors by prescribing simply the infusion of quassia as an injection. Tobacoeo elysters are praised; but the remedy is a hazardous one. Dr. Darwall says of an enema composed of half an ounce of the muriated tincture of iron mixed with half-a-pint of water, "there are few cases so obstinate that this will not suffice to overcome." Lime water, injected into the rectum, forms another efficacious remedy against ascarides.

Thread-worms may be scooped out of the rectum, with the finger. Old women fish for them with a piece of fat meat, or a candle, wherewith the entangled worms are drawn out of the bowel. Perhaps, in troublesome cases, the plan laid down by Martinet is as good as any. He recommends three successive injections: the first merely purgative; the second specific (common salt in solution, cold vinegar and water, lime water, some bitter infusion); the third, oleaginous and soothing. Oil often allays the itching. This teasing symptom may sometimes be quieted by applying a towel, wetted with cold water, to the fundament, while in bed.

With some means of this kind for expelling the worms, appropriate measures should be combined for improving the general health.

I know of no signs by which the presence, in the human intestines, of the *tricocephalus dispar* is revealed; and I am equally ignorant of any remedies for it.

That a *tape-worm* is within, we know when joints of it are voided. Numberless symptoms have been ascribed to this huge internal parasite. The following are probably the most distinctive. Uneasy feelings in the epigastrium, which often abate or are removed by eating; the appetite generally craving, but sometimes bad; itching of the nose, and of the anus; nausea; colic; giddiness; a sour breath. Less frequently loud borborigmi occur; and sometimes convulsions.

Louis has watched and recorded, with his accustomed minuteness, the symptoms of ten cases, in the wards of La Charité. Seven of the patients were males, and three were females. The youngest was a boy of twelve, the son of another of the patients; the oldest was seventy-four. Most of them were in comfortable circumstances, and had been habitually well fed. The greater number of them had for some time been passing fragments of tape-worm, with their stools, in their clothes, and in their beds. In one of the cases the articulations had been twice only detected in the stools, and each time upon the operation of a purgative.

In all the patients but two, the other symptoms commenced when the evacuation of the fragments commenced. This renders it probable that the worms begin to give annoyance when they get into the large intestine. The temporary relief that results from the expulsion of portions of the animal strengthens that supposition. In the

Medico-Chirurgical Journal is mentioned the case of a man who was in the habit of freeing himself from large fragments of tape-worm by introducing a stick into his rectum, and twisting the worm round till it broke.

The chief symptoms observed in Louis' cases were colicky pains of the abdomen; itching of the anus, and of the end of the nose; uneasiness in the epigastrium; and deranged digestion and appetite.

Pain in the abdomen occurred in *all* the instances: but it differed in different cases, both in degree and in kind. It was intermittent; and mostly felt towards the flanks.

There was itching at the margin of the anus in seven of the ten cases; itching of the nose in four. With one exception only, itching was present in one or the other, or in both of these situations.

The appetite was craving in one patient; unaffected in four; variable or bad in all the rest. In all, slight emaciation was observed. In all, the pupil of the eye was of its natural dimensions. This is noticed, because dilatation of the pupil has been set down as one of the symptoms of *tænia*.

Louis thinks that the following combination of symptoms indicates with tolerable certainty the presence of some kind of worm in the intestines. Pain in the belly; colic of various degrees of intensity, unaccompanied by diarrhœa; itching about the anus, and at the end of the nose. If pains in the limbs, lassitude, and nervous symptoms exist also, the diagnosis is strengthened.

We have a very effectual remedy for *tænia*—at any rate for the tape-worm of this country—in oil of turpentine, given in large doses. The anthelmintic virtues of this substance were not generally known till a paper on the subject, by Dr. Fenwick, of Durham, was published, in 1811, in the *Medico-Chirurgical Transactions*. A sailor, plagued by this parasite, had noticed that large fragments of the worm were passed whenever he had swallowed an unusual quantity of raw gin. Thinking that a stronger spirit might have a stronger effect upon his internal enemy, he tried a glass of turpentine, which completely cured him. This practice was then taken up by some unprofessional persons, who gave turpentine, with similar success, in several cases. At last Dr. Fenwick, in conjunction I believe with my friend Dr. Southey, investigated the subject; and when they had satisfied themselves of the value of the remedy, the result of their inquiries was communicated by Dr. Fenwick to the late Dr. Baillie, in a letter which was read before the Medical and Chirurgical Society. But there is nothing new under the sun. Fifty years ago, Mr. Malden, in the *Memoirs of the London Medical Society*, recommended the same remedy, in the same doses, for the same purpose. But his recommendation had been neglected, or forgotten.

The dose of turpentine is from half an ounce to two ounces. It may be given in combination with castor oil; or castor oil may be administered afterwards to assist its purgative effect. It should be taken in the morning, fasting; and no drink should be admitted into the stomach until the medicine begins to operate, lest sickness and vomiting should be provoked. The worm generally is voided, dead, within an hour or two.

The inconveniences of turpentine as a remedy are its nasty taste, the sort of intoxication it is apt to produce, the distressing sickness it excites in some persons, and the strangury it sometimes occasions. This effect of it, however, is less common from large than from small doses of the oil. The bowels should be kept open with castor oil, so long as the urine retains the violet smell, which indicates the presence of the turpentine in the circulation.

Upon the continent a celebrated empyreumatic oil, called Chabert's, is in great repute. It contains turpentine; but is still more nauseous than it. One part of the empyreumatic oil of hartshorn is mixed with three parts of oil of turpentine. After the mixture has stood for three days, three-fourths of it are to be distilled over, in glass vessels, by means of a sand-bath. Chabert was a veterinary surgeon; and had used this remedy with remarkable success upon domestic animals, cows, dogs, and sheep. Bremser, after testing its safety by taking it himself, administered it, he tells us, to no less than 500 individuals troubled with *tænia*. Among these were two children, a year and a half old. He found it both a powerful and a permanent cure. Of the whole number treated there were but four who required a second course of the remedy. The dose is two teaspoonfuls, night and morning, until four or six

ounces have been taken; a purgative being from time to time interposed. If that dose produce any confusion of head, it must be diminished.

Bremser admits that this curative process is tedious, but affirms that, on the other hand, it is safe, and but little inconvenient. When the patient has continued free from any symptoms of tape-worm for three months, he concludes that the cure is absolute. Other practitioners agree with him in attesting the efficacy of this oil; but are not so confident about its perfect safety and convenience.

Another great remedy is the bark of the pomegranate-root. This is at least as old as the time of Celsus. It has long been employed in India. Its value has only been recently appreciated in France; and in this country it is not much used, I believe, even yet. You may read a very instructive account of its effects in a paper communicated to the Medical and Chirurgical Society by Mr. Breton. He boiled two ounces of the fresh bark of the root in a pint and a half of water, till the decoction was reduced to three-quarters of a pint. Two ounces of this, cold, he gave to a patient who had tape-worm, and repeated the dose every half hour until four doses had been swallowed. About an hour after the last dose, an entire *tænia* was voided, alive.

The bark dried in the sun he found still more active. A stout man, forty years old, took a decoction prepared in the same way as the former, only with the dried instead of the fresh bark. Three hours after the first dose a live tape-worm came away, nineteen feet two inches long. The medicine thus prepared seemed to be too strong; the patient was sick, giddy, and trembling for several hours. He, also, had taken four doses.

To two boys, of seven and ten years of age, he began early in the morning to administer one ounce of a decoction made of half the previous strength, every half hour, for six times; and then stopped. In the middle of the day he resumed the medicine in half-ounce doses. Giddiness and faintness soon came on; and, about five o'clock, each of the patients passed a *tænia* of the *solium* kind.

A scruple of the powder was given, mixed with water, every hour, for five successive hours, to a boy of nine. Forty minutes after the last dose a living *tænia* was expelled.

The same quantity was given to a girl, ten years of age; beginning at eight, and repeating the dose hourly till twelve o'clock. At twenty-four minutes past one she voided a living *tænia lata*: and the next morning, at nine o'clock, a dead *tænia solium*. This curious case shows that the two species may exist in the same person at the same time.

Mr. Breton relates other examples; but those which I have cited are quite sufficient to demonstrate the power of this substance. The bark appears to act upon the worm as a poison. In tepid water *tæniæ* will live for several hours. When they are plunged into the aforesaid decoction, they writhe and manifest great uneasiness. Between the first dose of the medicine and the expulsion of the worm the shortest period appears to have been three hours, the longest twenty-five.

Louis' ten cases, before referred to, were all treated by a nostrum called the potion of M. Darbon. It proved successful in all. Eight or ten ounces of it were taken in the morning, before breakfast; and the cure was accomplished by that single dose. It is said to be quite safe, to have no very decided taste, and to cause no further inconvenience than a slight colicky feeling, and uneasiness in the epigastrium, less than is produced by many a purgative: and even these sensations were probably owing to the movements of the worm; for when, after the lapse of four months, the dose was repeated, it was followed by no inconvenience at all. The medicine is not strongly cathartic, and sometimes requires the aid of a lavement. In each of these cases the expelled *tæniæ* were apparently dead. Their *heads* were detected in the evacuations: in one instance seven heads were seen. Louis says that within a few days at furthest after the discharge of the worms, all the previous symptoms of their presence ceased; and the patients improved in respect of appetite, digestion, complexion, flesh, and strength. They all remained well four months afterwards, and then the potion was again administered; but it brought away no more worms. Some of the patients, who had previously tried other modes of cure, had never enjoyed so long an interval of freedom.

In 1850, a new vermicide drug was introduced from France into this country, consisting of the dried flowers of a tree that abounds in Abyssinia, where they have been

employed as an anthelmintic for more than two centuries. Kousso, in the Amharic language, is the name both of the tape-worm, and of the remedy. This has been tried by several English physicians, but first and most frequently by Professors Budd and Todd, in the King's College Hospital. In every instance, so far as I am informed, a single dose of the medicine has been followed by the expulsion of the worm, or of a great part of it. Its action is attended with but little distress, often with none. Occasionally it has caused nausea; sometimes it has proved gently aperient; and sometimes the aid of a subsequent purgative has been found requisite. It appears to be more uniformly successful than turpentine,—while it is much less offensive to the palate, and less rough in its operation. *Tæniæ* have been dislodged by it where turpentine had failed, or had lost its previous power. A patient of my own, a young military officer, was plagued with tape-worms in India. He had been in the habit of taking turpentine, which at first brought away portions of the animal, but after a while it failed entirely. Upon returning to England he took a dose of the kousso, a quarter of an ounce; and in four hours a worm, twelve feet long, was voided alive. But the symptoms recurred, and he then swallowed a second dose, with a similar result. A third dose, taken a fortnight afterwards, simply purged him. He assured me that, irrespective of its vermifuge property, he found the kousso far less unpleasant and annoying than the turpentine had been. In but few instances has the head of the parasite been noticed in the evacuations; but portions of its narrow part, near the head, often. Neither has the kousso always achieved a radical cure. Both kinds of *tænia* have been expelled by it; and being certainly effectual for the time, and both speedy and safe in its operation, it will no doubt be largely used here now. At first its cost was an impediment. Thirty-five shillings an ounce was the price, and half an ounce the dose. Much smaller quantities have however been found insufficient, and an ounce of the dried flowers may now be obtained for twenty pence. The powdered flowers are steeped in half a pint of lukewarm water for a quarter of an hour, and then the whole of the mess is swallowed, powder and infusion together. Lemonade is recommended to be drunk, both before and after the dose; why, I do not know, unless it be for compensation to the palate. It is well with this, as with every other weapon against tape-worm, to take the enemy at a disadvantage by using the remedy in the morning—an aperient having been premised the day before. The worm is thus less likely to be defended against the access and contact of the drug, by food, or by the intestinal secretions.

Various other remedies have been employed, and employed with more or less success. One of them, the root of the male shield fern, formed the basis of a nostrum, called Madame Nouffer's, which was so highly thought of, that in 1776 the King of France gave that lady some hundred pounds sterling for the secret of its composition. This ancient fern-remedy has had a very fluctuating reputation, in consequence probably of some imperfection in the manner of preparing it. It is, however, a valuable vermifuge, and likely to become the favourite remedy, in this country at least. Bremser thought that it was especially powerful in expelling the *tænia lata*: but against this opinion we may set the experience of Dr. Gull, who in a recent volume of the *Guy's Hospital Reports* gives the results of the employment of an ætherial tincture prepared from the *rhizoma* of the male fern, in 200 cases, among the patients of that hospital. He states it to be a convenient and an effectual remedy, succeeding where other anthelmintic drugs had failed; and out of fifty tape-worms expelled under its use, forty-nine were of the English, and one only of the Swiss species. From a drachm and a half to two drachms of the tincture was the common dose. It caused some nausea, occasionally even vomiting, and then it operated as a purgative. Dr. Willshire confirms Dr. Gull's estimate of this substance, and pronounces it to be less nauseous and irritant than turpentine, more sure than pomegranate, less bulky and less expensive than kousso.

LECTURE LXXV.

Diseases of the Liver. Acute Inflammation. Abscess of the Liver. Causes and Treatment of Acute Hepatitis. Chronic Hepatitis. Jaundice. Its Symptoms, Causes, and Species.

FROM the alimentary canal I go to the other organs directly or indirectly concerned in the digestion and assimilation of our food. And first, let us look at that large gland, the liver, of which the most obvious office is the secretion of bile. Modern science has, however, discovered that it plays an important part in perfecting the process of blood-making. Sugar is formed, and poured into the venous blood between its entrance into the liver through the portal vein, and its exit from the liver through the hepatic vein.

The liver is liable to various forms of disease: but it is not so frequently in fault as many would have us believe. It is often blamed most gratuitously and unjustly.

The researches of Mr. Kiernan, recently published in the *Philosophical Transactions*, have paved the way for a better understanding in future of its pathology. If I did not feel myself too much circumscribed by the remaining limits of this course of lectures, I should be glad to attempt to assist you in construing Mr. Kiernan's somewhat difficult and very valuable paper. But doubtless you are made familiar, in other lecture-rooms, with the anatomy of the organ, as described by him: and I must content myself with noticing, as we go along, one or two points, in respect to its morbid appearances, concerning which, before Mr. Kiernan took the subject up, great mistakes prevailed, even among the most celebrated pathologists.

I shall follow the usual order, and consider first, *inflammation* of the liver, which may be either acute or chronic.

These are, both of them, diseases that are much more common in warm climates than here.

Of well-marked acute hepatitis the symptoms are fever, with pain and a sense of tension in the right hypochondrium, inability to lie on the left side, difficulty of breathing, a dry cough, vomiting, hiccup.

You will not find all these symptoms present in every case: yet they are all worth attending to.

The pain is sometimes sharp and pricking, like a pleuritic stitch: sometimes dull and tensive. In the former case the peritoneal covering of the gland is supposed to be affected; in the latter its parenchyma. The pain sometimes extends to the right clavicle, and to the top of the right shoulder. This circumstance was noticed by Hippocrates; and I have referred to it before as a good example of what are called sympathetic sensations. The existence of this pain makes it probable that the inflammation affects the convex surface of the right lobe of the liver. Occasionally the *left* shoulder is painful: the left lobe of the liver being involved in the disease. The pain in the right side is aggravated, often, by the movements of the diaphragm in respiration; and this explains the embarrassment of the breathing, and the short dry cough. Why the patient cannot well lie on the left side is obvious enough: all the connexions of the inflamed organ are then put upon the stretch by its weight. There are, however, some exceptions to this rule. On the under or concave part of the liver lies the pyloric extremity of the stomach; and that viscus often sympathizes with the hepatic inflammation: nausea and vomiting occur; and hiccup. The thoracic symptoms on the one hand, or the stomach symptoms on the other, may be expected to predominate, according as the convex or the concave surface of the organ is chiefly the seat of the inflammation.

Permanent rigidity of the abdominal parietes, especially on the right side—and, more particularly, rigidity of the right rectus muscle—is a symptom strongly indicative, according to Mr. Twining and other surgeons in India, of deep-seated abscess of the liver. The same symptom was noticed by Dr. Budd in a case of jaundice from closure of the common duct, and in a case where a cancerous ulcer of the stomach had

caten into the adherent liver: and by Dr. Graves in a case of inflamed gall-bladder. This sympathetic affection is but one instance among many, of that kind of protective instinct whereby a tender part is in some measure shielded against the infliction of pain by pressure.

The situation of the pain, the cough, the short and shallow breathing, used to puzzle the older observers: and they confess their occasional inability to determine whether the inflammation was situated in the lower lobe of the right *lung*, or in the *liver*. But now-a-days we need have no difficulty in making the diagnosis. The ear will tell us, if we employ auscultation and percussion, whether the contents of the chest or of the belly are suffering: and my own experience has taught me that sharp pain, with feverishness, occurring in the debateable ground of the right side, denotes pleuritic inflammation far more often than it denotes hepatic.

Jaundice is an *occasional*, but by no means a *necessary* effect or accompaniment of hepatitis; whether acute or chronic: and, therefore, what I have to say of that symptom I shall give under a separate head.

Acute hepatitis may terminate in resolution; or it may terminate in diffused suppuration; or, what is more usual, in the formation of a circumscribed abscess, or of abscesses, in the liver. In this climate we do not often meet with hepatic abscesses; but they are very common in hot countries: and some of the most interesting events of the disease have relation to the progress of these collections of matter. When they approach the surface of the liver, adhesions generally take place (in virtue of that conservative principle of which we so constantly discern the working) between the diseased organ and the neighbouring parts. If no such adhesion occurred, the matter would at length burst into the cavity of the peritoneum; and this *does* sometimes happen. The peritonitis which is thus, suddenly, set up, is almost always fatal. I referred, however, in a former lecture to one instance in which it was recovered from. Sometimes the adhesion is effected between the liver and the parietes of the abdomen, and the abscess points *externally*, and may be opened by the surgeon. Such a case occurred in my neighbourhood last year. Sometimes the liver glues itself to the stomach, or to the intestines; and then the abscess breaks into the alimentary tube, the matter is evacuated by vomiting, or by stool: and all goes on tolerably well again. In other instances the agglutination is to the diaphragm, which is perforated, and the pus makes its way into the sac of the pleura, or through the lung to the bronchi, and so out by the mouth. I have seen three or four examples of this myself. In one the abscess originated in the formation and suppuration of a hydatid tumour in the liver; and the patient (a woman, she was under Dr. Maemichael's care in the Middlesex Hospital) spat up quantities of yellow fluid, consisting partly of pus, and partly of pure bile. The examination of the dead body ultimately demonstrated the nature of that case. In an instance of a similar kind, which has fallen under my cognizance of late, even while these pages were in the printer's hands (April, 1848), a more fortunate result may fairly be anticipated, although hydatids from the liver have made their way both into the alimentary canal and into the thorax. A surgeon from the country, aged 38, came to my house, and told me the following curious history:

For eight or ten years, at intervals varying from ten to fourteen months in duration, he suffered a series of attacks precisely resembling such as are commonly produced by the passage of a biliary concretion through the excretory ducts of the liver. In May, 1847, just after one of these attacks, while searching for a gall-stone, he discovered among the excretions from the bowels, two or three small hydatids. In July he again experienced for four or five days the same train of symptoms, and then vomited a green hydatid, as large as a pigeon's egg, but more elongated. Soon afterwards a short dry cough set in, with pain in a circumscribed spot on the right side of his back, and also at the tip of the right shoulder. These pains became very severe, and in the first week of August he expectorated, with coughing, matters which were yellow in colour, and bitter in taste; and after another week he spat up a hydatid like a grape. Pressure upon the hepatic region posteriorly, always produced an immediate paroxysm of coughing. This state continued for six or seven weeks, and during that period he expectorated some hundreds of hydatids, of which there are specimens preserved in the Museum of the College of Surgeons. At the conclusion of the fourth week he began to cough up from time to time large quantities of bile. The hydatids

ceased to appear towards the end of November; the bile, in the second week of February last. Once he coughed up four ounces of blood.

When I saw this gentleman he still had some cough, and expectorated mucus streaked with blood, and felt some pain in the situation of the liver. He was recovering his lost flesh. His pulse had never been much accelerated: nay, while he was coughing up bile, and voiding none at all by the bowels, it fell to 49 beats in the minute, and remained at that frequency for five or six weeks, until bile again began to be visible in his stools. During the same period the urine was very dark-coloured, and extremely scanty, not exceeding six ounces in twenty-four hours.

Milk and eggs appeared always to cause a great increase in the quantity of bile secreted and discharged. A similar increase was produced within five minutes of his taking any kind of acid. Magnesia as constantly reduced the quantity.

It is a remarkable part of Mr. L.'s history, that throughout all this illness he carried on a large country practice. For weeks he scarcely slept at all. While at the worst, and living upon a very slender diet, he began for the first time in his life to have *acne rosacea* of the face.

This brief account I took down from his own lips. The case is so full of interest that it deserves to be recorded in more complete detail.

It is plain that in such instances as these, there must be adhesion of the *lung* to the diaphragm also: but cases have occurred in which the matter burst into the cavity of the pleura, and presently destroyed the patient by suffocation.

The event of a third case is also still *sub judice*. A gardener, forty-five years old, was attacked, four weeks before he came under my care in the hospital, with severe pain in the right loin. Just at the edge of the short ribs, and not far from the vertebral column, on the right side, I found a large elastic swelling, very tender, and of a bluish red colour. As the patient's urine was most remarkably loaded with amorphous deposits, my first suspicions turned towards the kidney. It soon, however, became evident that, although the tumour was below the diaphragm, the parts above that muscle were involved in the disease. The right half of the thorax was dull to percussion; no vesicular breathing was audible there, but some scattered crepitation and bronchophony. Four days subsequently to his admission the patient began, during an effort of coughing, to discharge almost in a stream, from his mouth, a considerable quantity of grey, pultaceous fluid, of the consistence of gruel, and horribly fœtid. Altogether the amount of matter thus expectorated was estimated at two quarts. The pain then ceased; and the swelling was observed to be less. After three days more, it was deemed proper to puncture the tumour, and matter was let out having precisely the qualities of that which he had ejected through the mouth. The patient remained eleven weeks in the hospital, the expectoration becoming less unnatural, and the discharge from the abscess gradually diminishing. He then chose to depart. Some months afterwards he applied for re-admission, and again staid with us a week or two. His health had much improved during the interval: but the wound in his back was still open, and he still continued to expectorate somewhat; and yellow bile was frequently to be seen, both on the dressings which covered the puncture, and in the vessel into which he spat. I think it probable that this man may eventually recover, at the expense, however, of a permanently damaged lung.

A kitchen-maid at the Thatched House Tavern, in St. James' Street, received a violent blow at the back part of the right hypochondrium. This was followed by pain there, and by fever; and at length she began to have cough and dyspnoea, and to expectorate. She was taken into the hospital. Here she brought up an abundance of frothy mucus of a bright yellow colour; not at all resembling the rusty sputa of pneumonia, but exactly of the tint which bile would give to it. At the same time large crepitation could be traced from the bottom to the top of the right lung. I fully expected that this woman would die: but by degrees the yellow expectoration ceased, all the auscultatory signs gradually disappeared, and she recovered perfectly.

I thought, at the time, that this also might be a case of perforation of the diaphragm and of the lung, connected with the formation of an abscess in the liver. And the absence of jaundice, to which the colour of the matter expectorated might be imputed, lends likelihood to that supposition still. But I have subsequently met with a case in which similar symptoms presented themselves, without any hepatic mischief. A gentleman, beyond the middle period of life, was attacked with pain in the right

side, and with fever. He coughed also, and spat up some reddish sputa. Auscultation disclosed the existence of pneumonia in the lower lobe of the right lung. After two or three days the patient became deeply jaundiced; his skin presenting an orange-yellow hue. There was no deficiency of bile in the fæces; nor any pain, tenderness, or hardness in the hepatic region. Very tenacious mucus was expectorated, having a deep grass-green colour, with here and there patches of yellow. The inflammation extended to the upper lobes of the lung, and the patient sank. The lower lobe was found to be in a state of grey softening, or diffused suppuration, and it adhered, by a capsule of recent lymph, to all the parts around it. No appreciable change could be discovered in the liver, which contained rather less blood and bile than usual; nor in the gall-bladder and ducts. The secreted mucus of the air-passages had received its very unusual hue from the bile that circulated with the blood.

The sputa, collected in a basin, presented another appearance, such as I had never before seen. Large pyramidal bullæ projected among them, of green colour and crumpled irregular surface; looking like bells of moulded green glass. And when the summits of these large bubbles were broken through, the bubbles did not collapse; but their brittle walls remained firm, as they might have done if really vitreous.

Rigors occurring during the progress of hepatitis should make us suspect that suppuration is taking place: if the pain be thenceforward mitigated, or exchanged for a sense of weight, and if hectic fever set in, we may be tolerably certain that pus has formed.

Of the several courses taken by a hepatic abscess, that towards the surface of the body is the most common; and it is the only one with which we are able to interfere. And the chief thing we have to look to, is not to interfere too soon. The adhesion of the inflamed organ to the wall of the abdomen is the indispensable condition, not of success only, but of safety, where the question arises of puncturing the tumour. Without such adhesion the pus will be transferred from the cyst to the cavity of the peritoneum; or if the abscess be not reached by the scalpel, that cavity will be laid open. Now it is not easy to ascertain whether there be adhesion or not. Certainly the operation ought not to be attempted until the parts above the abscess are very thin, and are verging to a point; and even then, unless there were some distinct purpose, besides that of saving a little time, some urgent distress or danger to relieve, I think such abscesses might be more prudently left to themselves. Dr. Gregory, of Edinburgh, used to mention a case in which, as fluctuation was palpable, and the tumour pointed, it was proposed to open it; but the patient died, somewhat suddenly, before the operation could be performed; and inspection of the dead body showed that no adhesion existed. Mr. Malcolmson has lately published, in the *Medico-Chirurgical Transactions*, two or three instances of a like kind. These are circumstances which teach us to be cautious about recommending the operation. A plan was proposed and practised by the late Dr. Graves for *producing* adhesion, by making an incision over the centre of the tumour, down to within a line or two of the peritoneum. The same safeguard had been previously devised by Dr. Dick, in India, who made, however, the wound in the integuments by caustic, instead of by the knife.

A case is recorded of the bursting of a hepatic abscess into the pericardium; another into the vena cava. Facts of this kind constitute mere medical curiosities, and have no practical bearing.

It is clear, both from the size of the organ, and from its situation in the body, that an abscess in the liver can never be otherwise than gravely hazardous. Yet many recover from them. Much evidently depends upon the manner and direction in which the pus seeks and finds a vent. The most desirable road for its exit is one which it sometimes takes, but which I have not yet mentioned. It occasionally flows out into the duodenum through the excretory ducts of the liver, when these happen to have been laid open by the suppurating process. Next to this we may hope for its discharge through the adhering parietes of the abdomen; next by a breaking of the abscess into the alimentary canal. The escape of the matter through the air-passages is fearfully perilous; and its entrance into the shut serous sacs, or into the great blood-vessels, almost necessarily fatal.

I have spoken of abscess in the liver, as an event of acute inflammation of that organ. Such inflammation is apt to arise, in tropical countries, after exposure to cold. In any climate it may be excited by a blow, or other mechanical injury. But abscess in the liver seems to be far more frequently the result of other remote causes. You will call to mind those collections of matter which form in the liver, as well as elsewhere, in consequence of suppurative phlebitis. There is, moreover, an acknowledged connexion between hepatic suppuration and *dysentery*. In hot climates the two are often found coincident. It has commonly been thought that, in these cases, the affection of the liver happens first, in the order of time; that the hepatic disease, interfering with the freedom of the portal circulation, occasions congestion of the sub-mucous capillary blood-vessels, and so disposes the membrane to take on inflammation under the influence of any slight exciting cause. Dr. Budd, however, has proved, by a careful collation of a large number of authentic instances, that the relation of these two morbid conditions to each other, is exactly the reverse: that the dysentery is the primary disorder, and the hepatic abscess the secondary; the link of connexion between them being the same as between suppurative inflammation of a vein, and the formation of pus in parts more or less remote. The blood, in its return through the veins which are tributaries of the vena portæ, carries with it, if not pus, yet some vitiating ingredient from the inflamed membrane: and this vitiating ingredient provokes inflammation in the capillary vessels of the liver.

It is not, however, upon dysentery only that suppurative inflammation of the liver is apt to supervene; but upon various other morbid conditions also of the extensive mucous surface from which the returning blood is poured into the portal vein; upon injuries, therefore, (including surgical operations,) to the rectum, and the parts adjoining it, and especially upon ulceration of the intestines, of the stomach, and of the gall-bladder or its ducts. Yet not every form of ulceration: for abscess in the liver does not occur with that half-sloughing, half-ulcerating state of the glands of Peyer, which is so common in one species of continued fever; nor with that curious sort of ulceration of the duodenum, originating apparently in the glands of Brunner, which Mr. Curling has shown to be a frequent consequence of external burns; nor with the intestinal ulceration (still primarily glandular) which belongs to phthisis; nor are such abscesses often met with in connexion with simple ulcer of the stomach.

This, to the best of my knowledge, is a new, and certainly it is an important, view of the pathology of hepatic abscess. You will find, I say, the evidence upon which it is founded, fully developed in Dr. Budd's able and comprehensive treatise upon the diseases of the liver.

Acute hepatitis, when it occurs, requires vigorous treatment in the outset. Our object is, if possible, to prevent suppuration. Blood should therefore be freely taken from the system by venæsection, and from the neighbourhood of the inflamed part by leeches. I will not weary you by going over the old ground that we have so often trodden already, nor repeat observations which have been many times made respecting the methods, and the requisite amount, of this great antiphlogistic remedy. Depletion of the portal vessels may also be indirectly obtained by purgatives; especially by such purgatives as produce copious and watery stools. The neutral salts are therefore proper in this disorder. It may be, as some suppose, that they operate beneficially, as counter-irritants, upon the duodenum; but their effect in draining the veins that feed the vena portæ, and thereby relieving the hepatic congestion, is more obvious and more intelligible. These saline medicines should be much diluted; and their action may be quickened, if that be necessary, by adding the infusion of senna.

After blood-letting has been duly performed, and the force of the inflammatory action has been broken, blisters may be applied to the right hypochondrium: and I believe that repeated blistering is more serviceable than a single blister kept open by savine ointment.

Some difference of opinion prevails among medical men in regard to the employment of mercury in the *outset* of acute hepatitis. I cannot pretend to offer you the results of my own observation on this point, but I find that the best authorities, among those who have had to treat the disease in hot climates, are *against* its use at the *very first*, as being stimulating to the liver. I suspect that this is a piece of theory: but at all events, after the first violence of the inflammation has abated, that remedy is not to be omitted, either in the acute, or in the chronic form of the dis-

order, to be mentioned presently: only in the one case it should be so administered as to affect the system as speedily as possible; in the other it is to be introduced with a slowness which bears a proportion to the place of the disease.

When suppuration has taken place, or is unavoidable, when the patient ceases to complain of pain, but has in its stead a feeling of weight in the hypochondrium, and becomes distinctly hectic, a corresponding change must be made in the treatment. Active depletion is no longer admissible, and mercury must now be avoided: you must sustain the strength by a more nourishing diet, and prescribe some tonic remedies; the sulphate of quina, with sulphuric acid; or the nitro-muriatic acid, which enjoys a considerable repute, greater perhaps than it merits, for the relief of liver complaints.

Acute inflammation of the liver is apt to degenerate into *chronic*. Chronic inflammation may also arise under the circumstances that gave birth to the acute form. Chronic hepatitis, again, is not unfrequently produced by the presence of specific disease in the liver; of carcinoma; of scrofulous tubercles. Melanosis and hydatids are both of them of common occurrence in the same part; and they may give rise to symptoms, or they may not: and when these morbid conditions do declare themselves by external signs, those external signs are very much the same as belong to chronic hepatitis. The precise diagnosis is sometimes exceedingly obscure; the symptoms point distinctly to the liver as the *seat* of the disorder; but as to its exact *nature*, we must often be content with probabilities alone.

The symptoms of chronic hepatitis—or of the chronic forms of disease to which I have alluded, when they show themselves by symptoms—are (I give you them in Cullen's words) “some fulness and some sense of weight in the right hypochondrium; some shooting pains felt at times in that region; some uneasiness or pain felt on pressure in that part; some discomfort from lying upon the left side; perhaps some degree of jaundice; and sometimes a certain amount of fever combining itself with more or fewer of these symptoms.” In short, they are just the symptoms of acute hepatitis occurring in a minor degree.

Chronic affections of the liver are sometimes attended with an *increase*, and sometimes with a *diminution*, of its *size*. When it is augmented in bulk, its place and enlargement may be ascertained by palpation and percussion; nay, the magnified gland may sometimes be seen, extending beyond its proper situation in the hypochondrium, and passing far down into the abdomen. I have known the liver reach to the right groin: and when its left lobe is affected, it will sometimes stretch across towards the lower part of the left side of the belly. On the other hand, the liver may shrink into a much smaller space than it naturally occupies. These small livers are usually hard. Interfering more with the portal circulation than many enlarged livers do, they are more frequently attended with dropsy of the peritoneum.

FIG. 132.

Fibres originating from nuclei from fibrous tissue of a cirrhotic liver. Some cells are figured of the natural size, others are very much atrophied.

FIG. 133.

Cirrhosis of the liver. From a specimen in Dr. Gross' collection.

The "hobnail" liver, the *cirrrose* of modern French writers, is nodulated as well as hard. The irregularity of its surface may be so great as to be perceptible to the touch. I fully described this condition of the liver when I was upon the subject of passive ascites, of which it is the most common cause.

When a large round boss can be distinguished, projecting from the surface of the liver, we may speculate upon its being caused by a collection of hydatids; especially if the tumour has arisen without pain, or fever, or any material interference with the general health. When several smaller prominences can be felt, rendering the enlarged liver uneven, and the patient's health is broken, they are probably cancerous; and we search after tokens of cancer, elsewhere. A smooth, globular, painless tumour perceptible by the fingers near the margin of the liver, suggests the likelihood of a distended gall bladder, especially if jaundice concur.

Hydatid tumours may occupy the liver during the greater part of a man's life without causing him much inconvenience or discomfort, and with no perceptible impairment of his health: or, they may keep him in perpetual jeopardy, and at length shorten his existence in one of several ways.

I stated in the last lecture that such tumours sometimes undergo what may be called a natural cure. In the dead body they present themselves apparently shrunken, and containing a dry or pastelike mass, with intermixed fragments of dead and shrivelled accephalocysts. The sac of these old and defunct tumours is often more or less ossified. In this condition they are inert, and comparatively harmless.

But the living tumours may burst, under external violence, or from internal erosion, or perhaps from the increasing pressure of their contents; and their bursting has exactly the same consequences and dangers which I have just pointed out to you as attending the rupture of hepatic abscesses: for the clear liquid contained in the accephalocysts is not less irritant to serous membranes than bile itself. Indeed hydatid tumours may be converted into abscesses, by the occurrence of suppurative inflammation of the inner surface of their proper sac. The experience of Dr. Budd and of M. Cruveilhier concur in teaching that the most frequent cause of such suppurative inflammation is the entrance of bile into the sac through an ulcerated opening in a branch of the hepatic duct imbedded in its walls. Of this mingling of pus and bile and hydatids, and of the perilous passage outwards of these mixed contents of the tumour, through the lungs, and through the stomach and bowels, I have recently given you examples.

Of another possible and fatal consequence of the growth of these tumours you have also had an instance in the case, so often mentioned, of Harriet Baldwin, in whom the pressure of the distended liver completely stopped the return of the blood through the inferior vena cava.

One further point of interest I have to notice respecting these collections of hydatids. Concurrently with one (or more) of them existing in the liver, one or more have frequently been discovered in the lower lobes of the lungs, or in close contact with the spleen, or in some part of the mesentery; and seldom, if ever, in any other place. Now Dr. Budd has shown the great probability that in the majority of such cases the hepatic tumour has been the *parent* of the others: that *secondary* hydatid tumours in the lungs, in the liver itself, or between the folds of the peritoneum, may result from the transplanting, and subsequent growth, of hydatid germs which had found their way, through an ulcerated opening, into the hepatic, or into the portal, vein.

I mentioned some time ago, the "fatty" liver, so frequently found associated with pulmonary consumption. The liver in this state is soft, enlarged, smooth on its surface, and of a buff or tawny colour throughout.

[The *nutmeg* condition of the liver consists, in its best marked instances, of deep red congestion, forming patches and streaks, occupying the central parts of the lobules, and surrounded by patches of a greyish, or dirty white colour. The congested portions are most definitely limited, and the contrast between them and the pale parts is extremely striking. This probably depends on the circumstance that the portions thus devoid of blood are affected with fatty degeneration, a change which, by causing the cells to increase in bulk, occasions compression of the interwoven capillaries. That this is the true cause of the limitation of the congestion, is proved by its exactly

ceasing at the inner margin of the zone of fatty degeneration. The nutmeg appearance may be exhibited, in some degree, by livers which are quite free from fatty degeneration, but it is never so marked as in the latter case. — *Jones and Sieveking: Path. Anat., Amer. Ed., p. 507. — C.]*

Mr. Bowman has lately shown that these changes are owing simply to the unwonted abundance of certain small granules of fat, of which, in the healthy organ, each lobule contains a few only. If in a phthisical patient we find the liver palpably enlarged, and if we can feel no irregularity of its surface or of its edge, we may guess that it is encumbered with this interstitial fat: but there are no symptoms peculiar to the fatty liver. As to its cure, we are quite helpless: and the same may be said of the hobnail liver, as well as of all those forms of disease in which the organ is loaded with specific deposits.

FIG. 134.

FIG. 135.

FIG. 134. — (A) Section showing lobules of the liver, bounded by marginal zones in a state of fatty degeneration. The interior of the lobules is deeply congested, and contains much dark yellow pigment in masses.

(B) Cells loaded with pigment, atrophied cells and granular matter from the interior of the lobules.

FIG. 135. — Section of liver in a fatty state, with abundant new-formed fibrous tissue between the lobules.

FIG. 136.

FIG. 137.

FIG. 136. — Section of liver in an advanced state of fatty degeneration. The cells are much broken up and fused together.

FIG. 137. — (a) Empty envelop of an hepatic cell, from which the oil has escaped.

(b) (c) (d) (e) Hepatic cells containing much oil.

There is, again, the “waxy,” or “lardaceous” liver, of which also I spoke formerly, and which is characterized by the deposition throughout more or less of its substance,

of an albuminous material, rendering it large, and smooth, and of a whitish colour within and without.

This morbid condition, when it can be recognized in its earlier stage, is not, perhaps, quite so hopeless. Both Dr. Budd and Dr. Graves believe that the disease is, sometimes, at least, within the reach of remedial measures: among which, besides careful regulation of the diet and habits of living, the muriate of ammonia, the iodide of potassium, and minute doses of mercury, seem the most promising.

Dark masses of extravasated blood are sometimes found interspersed through this gland, and then, by an absurd perversion of language, the patient is said to have had "apoplexy" of the liver.

The same causes which produce acute hepatitis, acting in a less intense degree will excite chronic inflammation of the same textures. Intemperance also, and particularly the habitual and excessive use of alcoholic liquors, certainly tends to generate hepatic inflammation, especially in its more chronic form. We see this even here, and it is still more strikingly perceptible in warm climates, as you may learn by reading the works of those persons who have had experience of the diseases of India. Dr. William Ferguson, for example, who was for some time chief of the medical staff of the Windward and Leeward islands in the West Indies, observed that there was a regular increase and aggravation of these chronic affections of the liver among the troops after they received their monthly pay, when they drank great quantities of ardent spirits; arrack in the East Indies, and rum in the West.

There has long been supposed to be what is called a *gin-drinker's* liver, in which a section of that gland presents an appearance very closely resembling the section of a nutmeg; and a good deal of useless speculation has been employed as to the nature of the change which has taken place in such cases. The nutmeg aspect of the liver is produced by the congestion of blood, and the retention of biliary matter. This combination is, indeed, very likely to arise under the daily stimulus of distilled spirits, but it arises under various other circumstances besides; and therefore it is no sure indication of intemperate habits. Of this we had sufficient evidence before Mr. Kiernan's observations were published. Again and again have I met with the nutmeggy liver, strongly marked, when there was reason to believe that the possessor of it had never transgressed the strictest rules of temperance in drinking: in young persons, for example, of both sexes, who certainly never had been dram-drinkers. Disease of the heart is a very obvious, and a very common cause of hepatic congestion. The true gin-drinker's liver is that which I have already spoken of as the hobnail liver.

FIG. 138.

FIG. 138. — Scirrhus of the liver.

FIG. 139.

FIG. 139. — Gin-drinker's liver.

You are aware that the congestion occurs under two forms, according as the branches of the hepatic vein, or those of the vena portæ are gorged; and that the former of these two conditions is very much more common than the latter. If both these sets of vessels are full, the liver is universally red. If the hepatic vein alone be the seat of the congestion, then in the centre of each lobule we see a red speck, surrounded by yellowish matter; the specks are isolated, the yellow colour is arranged in a sort of network. Whereas, if the portal system be greatly engorged, the red streaks will be continuous, and the yellow portions hemmed in by them, and isolated. I show you these distinctions in some specimens prepared by Mr. Kiernan himself.

I should have stated, when speaking of the signs of chronic hepatitis, what is sin-

gularly true of ehronic liver affections in general, that they are apt to be attended with much languor and lassitude, and a remarkable depression of spirits; and with that sort of dread, and apprehension of impending evil, which I mentioned as being a striking feature of hypochondriasis: the very derivation of which term marks its frequent connexion with hepatic disorder. There is sallowness of the complexion also; and sometimes emaciation.

The same remedies are adapted to the ehronic, as are proper for the acute inflammation of the liver: the comparative mode of their exhibition, however, differs somewhat.

General blood-letting is not often necessary or advisable, execept when more violent aggravations than usual of the inflammatory symptoms supervene. Topical bleeding, and blistering, are more expedient.

But the two main remedies to be tried in this complaint are mercury, and the saline purgatives, given in small doses, and repeated for a long time together. Five grains of blue-pill every night, or every night and morning; and as much of the sulphate of magnesia as will produce one or two watery stools every day, for weeks, perhaps, in succession. Patients are not so well content to bear this discipline when it is administered in boxes and phials, as *physic*; but they have more faith in the natural mineral waters: so that a residence at Cheltenham, or some such place, is exceedingly proper to be recommended in these cases; where the daily use of the waters may keep up a continual drain on the system of the vena portæ; and where relaxation from business, the amusements that are constantly going on, with change of scene and of society, may contribute to dissipate the hypochondriacal feelings which are so apt to render the subjects of ehronic hepatic disease supremely wretched.

Moderate exercise, in the open air, on horseback and on foot, should be encouraged. There is no doubt that hepatic as well as gastric derangements are fostered by sedentary habits. Tepid bathing is another expedient from which benefit may be hoped. In many instances it will be proper to make trial of Scott's nitro-muriatic bath.

Iodine has been thought of much use in certain kinds of hepatic disease; in those kinds especially which are connected with enlargement of the viscus. The iodide of potassium, or a mixture of the iodide and of iodine, or some of the combinations of iodine and mercury, may be given in such cases: or the *unguentum iodinii compositum*, or the *unguentum hydragryri iodidi*, of the Pharmacopœia, may be rubbed night and morning upon the hypochondrium. I have not seen much benefit from these forms of medicine myself in such cases; but they are said, by persons of experience and credit, to have been successful in their hands.

Tarazacum is also a drug which has been much employed in liver complaints since Dr. Pemberton's book on the diseases of the abdomen was published: and when well prepared, and taken for a long time together, I believe it often does much good. The Germans are very fond of giving the *muriate of ammonia* in small and frequent doses. They have the same belief in the virtues of this salt, in various disorders, as most English practitioners have in those of mercury; and what is curious, they attribute to it some specific influence upon the functions of the liver.

In the account that I have now given of the principal diseased conditions of the liver, I have not dwelt upon, nor included, all the changes of structure and appearance to which that organ is liable. There are various conditions which disclose themselves by no intelligible symptoms during life, of which the nature has not yet been determined, and of which the cure still remains to be discovered. At this advanced period of the course, and with no time to spare, I do not think it necessary or right to trouble you with the unprofitable discussion of matters that are not strictly practical.

I have mentioned *jaundice* as an occasional symptom both of acute and of chronic inflammation of the liver. But jaundice is spoken of, in general, as constituting, itself, a distinct form of disease. If we consider it in that light, its diagnosis is most easy. We have only to look upon our patient to know what is the matter with him. But jaundice depends upon various and very different morbid conditions; and looking to those conditions as the true objects of diagnosis, we find that the real nature of a given case of jaundice is often involved in very great obscurity.

Let us first consider the constituent features of jaundice, whether it be regarded as

a *disease*, or as a *sign of disease*. They are, yellowness of the skin and of the eyes; whitish or drab-coloured fæces; urine having the colour of saffron, and communicating a bright yellow tinge to white linen.

The characteristic yellow complexion is owing, no doubt, to the presence of bile, or at any rate of the colouring matter of the bile, in the circulating blood. And the deep tint of the urine is evidently derived from the same source. On the other hand, the paleness of the fæces is to be ascribed to the want of bile, which always exists in healthy and natural excrement. This last symptom is not, however, a constant one; there may be jaundice while bile appears in the stools. I shall explain how this is supposed to happen presently.

If you ever doubt, as you possibly may, whether your patient be really jaundiced, or only yellowish from sallowness combined with anaemia, you will look especially to the conjunctiva, and to the urine, both of which betray the yellow tint of jaundice very early and conclusively. The eye readily recognizes bile in the urine; but its presence may be ascertained, in questionable cases, by an easy chemical test. If sulphuric acid be added in sufficient quantity, the urine assumes a dark green, and afterwards a purple colour.

It has been made a question how the bile, or its colouring matter, comes to be visibly present in the blood, or rather in many of the tissues supplied by the blood, and in several of the other fluids of the body. The older and more general opinion seems to have been that the bile, after being formed in the liver, is first detained there, or in the gall-bladder, in consequence of some impediment to its excretion, and then re-absorbed, and carried into the circulation, and so conveyed to the surface, and to the parts in which the change of colour is observed. To numerous instances of icterus this explanation may fairly be applied. That bile is capable of being taken up by the absorbents we know: for when the cystic duct is permanently shut, the bile disappears gradually, but entirely, from the gall-bladder. The existence of some positive mechanical obstacle to the efflux of the secreted fluid is often ascertained; and even when none can be discovered after death from well marked jaundice, it is conceived that either the ducts of the liver might have been temporarily plugged up by inspissated bile, or a sort of biliary sand—or else closed, for a time, by spasm, or by some morbid condition of the duodenum.

But another theory has been advanced on this subject: first I believe in this country, by Darwin. It was afterwards revived by M. Chevreul, who has been followed by Mr. Mayo, and others. These pathologists are of opinion that the bile is formed, not by the liver, but in the blood: that the office of the liver is to strain off or withdraw the bile from the circulation, constantly, as fast as it is formed: just as the perpetual elimination of urea from the blood appears to be one great purpose of the kidneys. They hold, therefore, that jaundice manifests itself whenever the due separation of the bile from the blood is suspended or imperfect. Failing of its natural vent, this peculiar substance accumulates in the blood, seeks other outlets, is deposited in various places, and, in fact, partly escapes through unaccustomed channels. They speak of jaundice as a symptom of *suppression* of bile, while others consider it as a sign of *retention*; using these words, suppression and retention, in the sense in which they are applied to the secretion of urine. They maintain that the proper function of the liver, the abstraction of bile from the blood, may be arrested by alterations of the substance and structure of that gland; or by the obliteration or obstruction of the gall-bladder or ducts, impeding or forbidding the removal of the bile already collected; or by some obscure influence of the nervous system upon these organs. They introduce the last kind of cause with the view of explaining those cases, which certainly occur, in which jaundice is the result of severe bodily pain or strong mental emotion. Nay, on their supposition, we might even suppose that the yellowness is sometimes due to a spontaneous and unwonted *abundance* of the elements of bile in the blood: in which case we need not wonder that jaundice should go along with perfect integrity of the biliary apparatus.

There is little reason to doubt that this also is a well-founded theory in respect to some predicaments of jaundice. Dr. Budd even thinks it probable that, in the majority of all cases, that disorder “results primarily, and solely, from the secretion of bile being suppressed or deficient.” Chemistry, however, has never yet detected bile, or its principles, in the blood. Its pigment has indeed been found to be present

in blood drawn from *jaundiced* persons; but this fact has no bearing upon the question how this colouring matter came to be there. Nevertheless there may be—I quite believe there is—such a disorder as jaundice from suppression of bile. But in actual practice it is often impossible to determine, while the patient is still alive, whether the case be one of suppression, or of retention.

I pass from this digression to a somewhat closer examination of the principal circumstances noticeable in the complaint. Its technical appellation, I should observe, is *icterus*, which is the Greek name for a bird with a yellow plumage, the gull, or golden thrush; the sight whereof, by a jaundiced person, was death (Pliny tells us) to the bird, and recovery to the patient. Various other terms have been applied to the disorder, most of them having reference, like jaundice itself (from the French *jaune*), to the unnatural colour. *Morbus arquatus*, from its exhibiting some of the bright hues of the rainbow; *aurigo*, from its resembling gold; and we hear the common people say, now-a-days, such a one is as yellow as a guinea. The Latins spoke of it also under the title of *morbus regius*: why they so called it we learn from the following curious passage in Celsus, giving an account of the pleasant regimen, fit for royalty itself, to be adopted by those who labour under the malady. “Per omne vero tempus utendum est exereitatione, frietione: si hiems est, balneo; si æstas, frigidis natationibus; leeto etiam et conclavi cultiore, lusu, joco, ludis, lasciviâ, per quæ mens exhilaretur: ob quæ regius morbus dictus videtur.”

The whiteness of the stools I have mentioned as being a very common but not a constant appearance. It clearly depends upon the absence of bile. Such stools have often a sour and very offensive smell. But sometimes there is bile in the discharged fæces, and at the same time the yellow colour of the skin, and eyes, and urine. This probably depends upon the circumstance that some branches of the hepatic ducts are obstructed while the others are free; and thus the bile that is secreted is, in part, re-absorbed into the blood, and in part carried off into the intestines. In a former lecture I stated that one of the uses of the bile appeared to be that of stimulating the bowels to action: it is the natural purgative. Accordingly in most cases of jaundice, the bowels are costive. But neither is this uniform. In some of the worst cases, wherein the jaundice depends upon hepatic disease, which is connected with disease also of the mucous coat of the intestines, there is constant diarrhœa.

In some instances the yellowness of the skin is at first attended with itching, which is occasionally so intolerable as to require the employment of opiates to allay it. In most cases there is no itching at all. The bile never fails to appear in the urine, which is in itself dark, and when collected in considerable quantity in a deep vessel, even *black*; and which tinges any white substance that is dipped into it of a bright yellow. The urine which thus sometimes seems black, may be proved to derive that appearance merely from concentration of the yellowness, by pouring a little of it into a shallow white dish, or by diluting it with water; when the brilliant yellow tint will become manifest. Bilious sweat sometimes occurs, staining the patient's linen yellow. The saliva, in some jaundiced persons, has the same yellow tinge, and a distinctly bitter taste. Yet the secretions furnished by the mucous membranes are in general signally exempt from this change of colour. The tongue and inside of the lips present commonly a remarkable contrast with the face, of a jaundiced person. Dr. Budd observes that the mucus of the stomach and intestines is never stained with bile, except when that secretion has continued to enter the duodenum. I have already mentioned two or three instances that have fallen under my own notice, in which mucus brought up from the lungs was rendered green and yellow by bile: but this is of rare occurrence. It has been said that the milk of women who are nursing is made yellow in this disorder. Dr. Heberden, however, states that he never witnessed this; and he had known a woman with a very deep jaundice upon her, suckle her infant for six weeks together with no apparent bad effects upon its health. One man assured him that his tears were yellow. You are aware of the vulgar notion, suggested, no doubt, by the colour of the conjunctiva, that to a jaundiced eye all things appear yellow. It is an old notion, for we find it expressed by Lucretius:—“*Lurida præterea fiunt quæcunque tumentur Arquati.*” Heberden was disposed to regard this as a mere poetical fiction. But certainly it is sometimes, though very rarely indeed, a fact. Two women, whom he considered however to be of little credit, told Heberden that objects appeared yellow to them. I have been assured of the

same thing by a medical man who experienced it in his own person. If I do not mistake, Dr. Mason Good saw all things yellow when he was jaundiced. Dr. Elliotson has had some very interesting cases of this phenomenon. One of his icteric patients declared that objects seemed yellow when looked at with one eye, but not with the other; and in the eye that perceived the yellow tint he observed two large red vessels running towards the cornea. And in one or two instances, which he met with afterwards, of yellow vision with both eyes in jaundiced patients, he found inflammation, or distended blood-vessels, in both eyes. This very morning I saw in the hospital a patient of Dr. Wilson's, a middle-aged woman, affected with jaundice. She affirms that all objects seem yellow to her vision. In both eyes there are several varicose and singularly tortuous vessels, proceeding across the sclerotica towards the cornea, and some of them reaching its margin. It seems probable therefore that the ophthalmic vessels, in their natural state, do not permit the colouring matter of the bile to pass through them; but that when they become enlarged by disease, so as to admit the colouring particles of the blood, they may also give a passage to the yellow colouring matter, which tinges the humours of the eye: and in that case the objects seen through the yellow fluids would appear like those viewed through a piece of yellow stained glass. This is a point which is worth your attention in future.

The shades of yellowness are different in different patients. Those who are pale and fair present a bright lemon colour. But in those who are florid, or whose cheeks and skin are flushed with fever, the tint will more resemble that of the Seville orange. Again, if the patient be naturally swarthy, or if his visage be livid or dusky through imperfect arterialization of his blood, the superaddition of jaundice will give him a greenish or olive hue. These differences result from natural or acquired differences of complexion, antecedent to the icterus. But sometimes the bile that is re-absorbed is vitiated and dark; and we may have, for that reason, as Dr. Baillie has pointed out, cases of green or black jaundice. You will remark that from whichever cause the green or dark colour proceeds, whether from a mingling of the yellowness of the bile with the blueness of lividity, or from the circulation of green-coloured bile, such cases are especially unpromising cases.

Icterus depends, as I have said, upon various and different internal causes: and frequently we cannot determine at all, until death affords us the means of inspecting the parts concerned in its production, what the precise exciting cause may be; even when it is simply mechanical. Any kind of pressure made upon the excretory ducts of the liver will produce it: and such pressure may be exercised by tumours seated in the liver itself; or by a scirrhus pylorus; or by specific disease situated in the head of the pancreas, of which I have seen several examples; or by a diseased condition of the duodenum: and these possible causes of a detention of the bile in its receptacle should always be borne in mind when we are investigating an obscure case of jaundice.

The impediment, in the cases just supposed, is external to the ducts; but they may be obstructed within, plugged up by mucus, by inspissated bile, or by a biliary calculus. This forms one of Cullen's species of icterus—the *icterus calculosus*. The concretion is most commonly situated, I believe, in the ductus choledochus; sometimes, however, in the cystic, and sometimes in the hepatic duct. The pain that attends the passage of a gall-stone through these ducts is often dreadful. Perhaps there is no pain to which the body is subject that is more severe. You will not wonder at this, when you consider that through a tube, of which the natural size scarcely exceeds that of a goose-quill, there sometimes passes a stone as big as a walnut. The common duct has been found so dilated as readily to admit one's finger. Cullen's definition of this species is "*Icterus, cum dolore in regione epigastricâ, acuto, post pastum aucto, et cum dejectione concretionum biliosarum.*" Now the last of these circumstances, the

FIG. 140.

Gall-bladder and cystic duct, containing calculi, which have a crust of pure cholesterin. The two upper are divided.—From Dr. Budd's work.

Now the last of these circumstances, the

voiding of biliary calculi by stool, may happen over and over again, without its being noticed, and it does not help us at all to judge of the nature of the complaint at its commencement, while the gall-stone is still within the ducts. With the pain, which is not constant, but comes and goes, there is much nausea and vomiting; and sometimes hiccup; and the matters vomited are usually very sour. The patient is flatulent, and dyspeptic; languid, and gloomy. At length the concretion passes into the intestines; the pain suddenly ceases, and all is soon well again. Attacks of this kind, having happened once, are very apt to be repeated.

Now this pain you might readily mistake for the pain of inflammation, were it not marked by these two circumstances — the absence of tenderness, and the absence of fever. Pressure, instead of augmenting, usually mitigates it. The patient keeps his hand firmly applied to his epigastrium; or rests, perhaps, the weight of his body upon some hard substance placed beneath his stomach. I speak now of the beginning of the attack, before there has been much retching; for a degree of tenderness of the abdominal muscles is often produced by repeated straining and vomiting. The pulse is unaffected, or I should rather say it is not accelerated, during the pain: occasionally it is even slower than natural, and the skin cold. Though there be no inflammation, rigors may occur; just as they sometimes happen when a solid substance — a bougie to wit — is passing through, and distending the *urethra*.

Nevertheless, inflammation does sometimes arise, and then the pulse becomes frequent, and the skin hot, and thirst and head-ache are complained of, and the epigastrium is tender; and if blood be drawn it exhibits the buffy coat. Sometimes the gall-stone makes its way, by ulceration, through the contiguous structures, and so is discharged outwardly, or into the bowels. In such cases there must have been inflammation.

FIG. 141.

Calculi in the gall-bladder. From a preparation in Dr. E. Wallace's possession.

As jaundice often occurs without any pain, so a gall-stone may enter and pass through the ducts, and produce pain, when there is no jaundice. The cystic duct alone may be blocked up, and that portion only of the bile be prevented from escaping which is accumulated in the gall-bladder. It is probable that re-absorption of the contents of that cistern is not very active. Or a calculus of an angular shape may stick in the common duct, and thus

impede, without entirely stopping, the egress of the bile. Dr. Heberden thought that gastrodynia was not unfrequently owing to biliary concretions: founding his opinion upon the fact that many persons suffer, for months or years, under occasional attacks of epigastric pain, which is at last associated with jaundice. But after all, this might happen from progressive disease in the stomach itself; and it is a pity that Dr. Heberden's views were not fortified by dissections.

When once a large calculus has forced its way through the natural channels of the bile, they remain permanently dilated; and smaller stones may be afterwards voided without pain or other notice of their passage. There are persons who get rid of scores of them in this way, during the course of their lives.

Sometimes a large concretion, after its extrication from the biliary passages, lodges in the more capacious intestines, and gives rise to serious obstruction there. I mentioned, recently, one case of this kind which had fallen under my own notice. But in general the concretions are presently voided with the stools: and they should always be looked for. The patient is much gratified by *seeing* that his enemy has been expelled; and also by the proof he thus obtains of the sagacity and judgment of his physician. The *faeces* should be mixed with water, upon the surface of which any gall-stones that happen to be present may probably float, since they are specifically lighter than that fluid. It is justly remarked, however, by Dr. Budd, that although lighter than water when dry, they sink after having been soaked in it for some time, and do not always float when fresh from the gall-bladder. I formerly told you that I had never but once succeeded in catching a concretion in the evacuations of a patient,

whose symptoms had led me to seek for it. Since that statement was made, three other patients of mine, taught how to search, have detected among the alvine discharges, this palpable source and explanation of their previous sufferings. One of the three collected, in this way, fifty-five small faceted biliary calculi, which he voided within the space of five weeks. He was jaundiced; and he began to pass them, four or five at a time, with paroxysms of severe pain, just after having had the hepatic region diligently shampooed and kneaded as he lay on his left side in a warm bath; so that they seemed to have been mechanically pressed out of the gall-bladder, and through its ducts.

When concretions pass which are small and angular, having several flat surfaces, we are to expect that more will follow them. If a single stone come, large, smooth, and roundish, we may hope that it has left none behind it.

We often find gall-stones, even in vast numbers, in the gall-bladders of persons who during their life-time had never been known to suffer pain about the liver, or to have jaundice, or to exhibit any token of the presence of such concretions. We infer from this that, while they remain in the reservoir of the bile, they are harmless; and that the suffering and the hazard they occasion are mechanical consequences of their transit through the gall-ducts. I have heard of an instance in which upwards of 1,300 gall-stones were taken from a human gall-bladder after death.

On the first day of June, 1854, a remarkably strong and healthy man, between 60 and 70 years old, with whom I had for many years been on terms of friendship, was engaged in inflating an air-bed by blowing with his mouth through a tube. The process required a long-sustained straining effort, and he suddenly felt that he was hurt in the right side of the epigastrium, near the edge of the false ribs. After a while the pain ceased, but it recurred with severity in the night, and the next day his skin was slightly yellow. Bating some trifling and early variations in its tint, the yellow colour became deeper and deeper, and he remained intensely jaundiced till the day of his death, which was the 29th of the following August.

During his illness, his liver gradually became very large and prominent. His stools were devoid of bile, and his urine was charged with it. The pains continued to return from time to time. He had been subject to similar pains in his youth, and had been taught to ascribe them to "spasm of the diaphragm."

There was a good deal of fat about the abdomen. He did not die of inanition. The liver was enormously enlarged, and full of bile: and the gall-bladder, which was much thickened, was filled with numerous calculi, and moulded, as it were, upon their irregular form and outlines. One large gall-stone, something like a horse's hoof in shape, completely plugged up the opening of the common duct into the duodenum. Branches of the hepatic ducts in the liver were so distended as to present little reservoirs of bile and mucus. It seems probable that some of these calculi were of very old date. Here life was extinguished in thirteen weeks, by the mere occlusion of the biliary ducts, and the complete barring up of bile in the liver. Dr. Budd relates a case in which the body was tolerably well nourished for more than twelve months, although the common gall duct was closed all that while by a gall-stone; and another in which a woman, suffering under a similar obstruction, lived more than eight months in a state of deep jaundice, and five months after the occurrence of the jaundice gave birth to a child, which she was able to suckle up to the time of her death.

These gall-stones are not, as you might suppose, mere lumps of inspissated bile. There are, I believe, concretions of that kind, but they are very rarely met with in the human subject. The ordinary calculi consist, in a great measure, of a peculiar substance, *cholesterine*, which exists in a state of solution in healthy bile, but which in some morbid conditions of that fluid, being released from its solvent, assumes its proper crystalline form. Very little is known respecting the circumstances under which the change takes place. *Cholesterine*, Dr. Prout tells us, is the product of some modification of the oleaginous principle. Biliary concretions seldom form in children. They are much more common in women than in men. They occur most frequently in persons who are corpulent, lead sedentary lives, use generous fare, sleep

much, and neglect their bowels: all which things foster or denote a torpid and congested state of the hepatic system. Cattle are said to be subject to biliary calculi when shut up in stalls during the winter, and to lose the complaint when they are again turned out into the pastures in the spring. Hence the absurd notion, countenanced even by Van Swieten, that grass is a good remedy for jaundice.

Another variety of jaundice, also noticed by Cullen, is supposed to depend upon mere spasm of the gall-ducts. "*Icterus spasmodicus*, sine dolore, post morbos spasmodicos, et pathemata mentis."

Now the existence of this cause is hypothetical. The gall-ducts, though not distinctly muscular, possess a vital power of contraction. I am not aware that the disease has ever been clearly traced to a connexion with "*morbi spasmodici*." It is an alleged cause which we can neither prove nor disprove. Certainly the "*pathemata mentis*" play their assigned part: fits of anger, and of fear, and of alarm, have been presently followed by jaundice: and it has also been produced by great bodily suffering, by a severe surgical operation, or, perhaps by the dread which attended it. Mr. North witnessed a case in which an unmarried female, on its being accidentally disclosed that she had borne children, became in a very short time yellow. A young medical friend of mine had a severe attack of intense jaundice, which could be traced to nothing else than his great and needless anxiety about an approaching examination before the Censor's Board at the College of Physicians. There are scores of instances on record to the same effect: and *this* is observable of such cases, that they are often fatal, with head symptoms: convulsions, delirium, or coma, supervening upon the jaundice. But with respect to the immediate cause of the icteric symptoms, they may, I say, depend upon a spasmodic constriction of the gall-ducts. Mr. Mayo suggested another cause, viz., the sudden formation of bile in unusually large quantity in the blood, by some influence propagated through the nerves. Dr. Budd is of opinion that in the cases which prove fatal, with delirium and stupor, some peculiarly poisonous matter is evolved in the system, most probably from decomposition of the retained elements of the bile.

Jaundice sometimes succeeds violent and long-continued vomiting; in which case the extremity of the gall-ducts is supposed to have been compressed by the coats of the duodenum.

Jaundice may also occur, as I stated before, as a symptom of acute or chronic inflammation of the liver; and then its treatment will merge in that of the primitive disease which occasioned it.

A high atmospheric temperature, long continued, appears to have a decided influence in producing certain forms of this disorder. I was struck with the frequency of a mild and manageable kind of jaundice, which affected young persons, chiefly females between ten and sixteen years old, in this town, in the autumn of 1846, just after the prevalence of extremely hot weather.

Icterus occasionally comes on during pregnancy; and disappears after child-birth. The pressure of the gravid uterus may thrust other organs, a loaded colon for example, against the liver, and so impede the passage of the bile. The little exercise that pregnant women are apt to take, and the costiveness that frequently attends their condition, may have some influence in causing the *icterus gravidarum*.

Almost all systematic writers follow Cullen in making jaundice a common disorder among newly born children. The *icterus neonatorum* occurs, they say, a few days after birth; is not attended with any suffering, or obvious disturbance of the bodily functions; and soon disappears. Now there seems reason to believe that this is not icterus at all; and has no relation to the biliary organs. The surface of the infant, at its birth, is frequently of a deep red, from hyperæmia or congestion of blood; presenting a condition which falls little short of a mild but universal bruise. By degrees the redness fades, as bruises fade, through shades of yellow into the genuine flesh-colour. Such, I am assured by those who are more conversant with these matters than myself, is the pathology of the *icterus infantum*. Of course true

jaundice may, as well as most other complaints, befall the earliest period of life; but I conceive that it seldom does.

The prognosis in jaundice is generally favourable; except when it depends upon structural disease of the liver, or supervenes suddenly upon some great mental or bodily shock. In both these cases the prognosis is bad, or doubtful. It is better, in that variety connected with hepatic disease, if this disease proceed from some known cause, by which a low degree of inflammation has been produced; and the cause be such as can be avoided for the future. Just, indeed, as in chronic hepatitis, of which the icterus is simply an occasional symptom. The prognosis is worst of all in old persons, when the constitution is impaired, and there is no obvious cause for the disease; and particularly when the colour of the skin is greenish, or approaching to black.

LECTURE LXXVI.

Treatment of the various Species of Jaundice. Diseases of the Gall-bladder; of the Spleen; of the Pancreas. Diseases of the Kidneys. Nephritis and Nephralgia. Phenomena constituting a "fit of the Gravel." Different kinds of Gravel. Diseased states of the Urine. Description and Remedies of the Lithic, Phosphatic, and Oxalic Diatheses.

IN the last lecture, after describing the symptoms, causes, and treatment of acute and chronic inflammation of the liver, and after pointing out various other forms of chronic disease to which that organ is obnoxious, I spoke of *jaundice*. I offered you some comments upon its phenomena; and I indicated several different internal conditions upon which it may, in different cases depend; and the lecture was closed with some brief hints respecting the *prognosis* of icterus. I have yet to consider the plans of treatment best adapted to the several varieties of the complaint.

Some kinds of jaundice are absolutely and obviously irremediable. In these take care not to *harm* your patient by senseless routine formalities. From others the patients recover, whatever treatment may be adopted, or without any treatment at all. Hence, as is customary in such circumstances, remedies the most worthless and absurd are extolled for their efficacy against jaundice. The patient gets well, and the drug last tried is held to have cured him. *Post hoc, ergo propter hoc*, is an argument more often applied I believe to the variations of disease, than to any other class of events.

In that species of icterus which occurs, sometimes, in connexion with acute or chronic inflammation of the liver, the treatment must be such as I yesterday recommended for acute and chronic hepatitis. Mercury forms an essential part of that treatment; and, unless the disease yielded sooner, I should urge the remedy until its effect upon the gums, and, therefore, its presence in the circulating blood was apparent.

But to the icterus calculosus, mercury is not so well adapted. What we want is, not a more plentiful or a more healthful secretion of bile, but to get rid of the mechanical impediment to its excretion; or, at any rate, if that cannot be accomplished, to ease the acute sufferings of the patient. Should fever attend the passage of a gall-stone, or should the epigastric pain become epigastric tenderness, leeches may be applied, or a vein may be opened. The abstraction of blood may prevent any thickening of the distended gall-ducts; or it may perhaps relax the spasmodic closure around the calculus. But, in general, blood-letting is not requisite nor of service in this variety of jaundice. Our great resource for relieving the pain, and for loosening the presumed spasm, is opium, given in full doses: and I can add but little, with any advantage, to the directions laid down, on this head, by Dr. Heberden. "This pain (says he) can only be assuaged by giving and repeating opium and its preparations,

as often as the continuance of the pain requires them; and because this pain is very apt to return, the patient should always be advised to keep by him, as long as the distemper lasts, pills of pure opium, each weighing one grain—or what is equivalent to them—that no time may be lost in quiting a sensation which it is so difficult to endure. One of these pills may be taken as soon as the pain comes on, and it may be repeated once or twice in the course of two hours, if the pain require it; and I have often found it both safe and necessary to give much more.”

This plan of giving opium in the form of *pills*, is the more judicious, because, from their small bulk, they are more likely to be retained than draughts would be. Sometimes the stomach is so irritable as to reject even a pill. I would add, therefore, to Dr. Heberden's recommendations, that of throwing an opiate injection into the rectum; half a drachm or a drachm of laudanum, mixed with a small quantity of warm gruel. Another very useful expedient is the warm bath. If this cannot be readily procured, hot fomentations to the epigastrium, the mustard-poultice, the turpentine stupe, are valuable substitutes for it. Dr. Prout states that he has seen more alleviation afforded by large draughts of hot water, containing the carbonate of soda in solution (one or two drachms to a pint), than by any other means. “The alkali counteracts the distressing symptoms produced by the acidity of the stomach; while the hot water acts like a fomentation to the seat of the pain. The first portions of water are commonly rejected almost immediately; but others may be repeatedly taken; and after some time it will usually be found that the pain becomes less, and the water is retained. Another advantage of this plan of treatment is, that the water abates the severity of the retching, which is usually most severe and dangerous when there is nothing present upon which the stomach can react. This plan does not supersede the use of opium, which may be given in any way deemed most desirable; and in some instances a few drops of laudanum may be advantageously conjoined with the alkaline solution, after it has been once or twice rejected.” The pain having been quelled, the bowels should be swept out by a brisk purgative.

When jaundice appears to have been suddenly engendered, by moral causes, the rationale of its production is obscure; and the treatment has a corresponding uncertainty. The bile, retained or readmitted into the blood, is supposed to operate somehow as a poison upon the nervous system. But the mental state which precedes and seems to occasion the jaundice, may possibly be itself the cause of the nervous symptoms that follow. In other forms of the malady patients remain intensely yellow, often for a long time together, without becoming comatose, delirious, or convulsed. Not that this is conclusive. We know that a given poison may influence different persons, very differently. The same dose of opium that will put one man to sleep, will stimulate a second to madness, and will have no sensible effect upon a third. In the very complaint before us, one patient is tormented with a universal itching, which we attribute to bile in his blood; and ten others remain free from that disagreeable feeling. If we were sure that the bile was the material cause of all the cerebral symptoms, we might hope to draw some of the poison off by blood-letting; but we are not sure of this; and reasoning upon the matter helps us not much towards the cure. The lesson which experience has furnished amounts to no more than this: that active purging is sometimes followed by evident amendment, and ultimate recovery. I would bleed also, if the *pulse* warranted venæsection, but not otherwise. In all the varieties of what, from its intensity and rapid accession, I may call acute jaundice, purging is strongly indicated: and we sometimes succeed in rectifying the whole morbid condition by thus applying a sudden *wrench* (so to speak) to the biliary organs; by giving, for instance, half a scruple or a scruple of calomel, and, a few hours afterwards, half an ounce of castor oil, with half an ounce of spirit of turpentine.

When *green* jaundice arises from hepatic disease, we can only palliate. Mild laxatives and anodynes, with occasional warm baths to promote perspiration, comprise all that such a state admits of. For the *icterus gravidarum*, delivery is the natural cure: it may sometimes be removed by the careful employment of aperients.

[Mr. Twining, in his work on the Diseases of Bengal, has presented some very interesting and important views in relation to the pathology of jaundice.

Mr. T. has found that jaundice, not only during its early stage, but for a long period subsequently, while the discoloration of the skin remains, is very generally

attended with some morbid sensibility when pressure is made over the situation of the gall-bladder and capsule of Glisson, though the uneasiness, during the absence of pressure, is most generally referred to the epigastrium.

When the disease occurs in plethoric subjects, and the stools are of a pale clay colour, Mr. T. has found it almost always attended with fever, and in some cases he has known robust patients to die, with symptoms of oppressed brain, within thirty-six hours after the sudden appearance of intense jaundice, for the accession of which no cause could be assigned.

In consequence of the acknowledged obscurity which exists in regard to the true pathology of the disease, he was anxious to ascertain the exact condition of the liver and biliary ducts in persons labouring under jaundice. The almost invariable existence of pain, increased upon pressure, confined to a circumscribed spot on the right side, just below the centre of a line drawn from the right nipple to the umbilicus, led him early to suspect circumscribed inflammation of some part of the liver as the most frequent cause of the disease. This opinion he believed to be confirmed by the good effects which, in the majority of cases, are produced by a systematic course of depletion: nevertheless, if circumscribed inflammation be the efficient cause of jaundice, he found it difficult to explain why the disease was so frequently absent during the progress of the most unequivocal and intense inflammations of large portions of that organ. The examination of individuals who had recovered from jaundice only a short time before death occurred from other diseases, exhibited no appearances in the liver indicative of any circumscribed portion of it having been the seat of recent inflammation. In the course of his dissections, however, Mr. T. found that albuminous infiltration into the cellular structure of the capsule of Glisson was sometimes present. Within this capsule are situated two small bodies, which, from their structure, appearance, and uniformity of situation, he is inclined to believe are absorbent glands: one of them is situated near the termination of the gall-bladder in the cystic duct, the other, at the upper part of the ductus communis; the superior gland is sometimes very small, and occasionally, it is more closely attached to the side of the gall-bladder than to the cystic duct; the lower one is more uniform in bulk, being usually half the size of a small bean; it is always placed just at the orifice of the common biliary duct. Irritations affecting the absorbent vessels passing through this gland may, Mr. T. conceives, cause in it such a degree of swelling as would produce transient compression and closure of the common duct, and thus prevent the passage of the bile into the intestines, and give rise to the phenomena of jaundice. So long as the obstruction is complete, the stools will be nearly white, or of a very pale grey colour; when, however, the jaundice is attended with severe fever and symptoms of intense gastro-enteritis, the stools will very often be coloured by the blood which is poured out by the capillary vessels of the intestinal mucous membrane, as well as by other morbid secretions.

When previous inflammatory disease of the capsule of Glisson has caused an infiltration of coagulable lymph into the cellular structure of that part, at a remote period, and its subsequent absorption has left a degree of induration and constriction, Mr. T. believes that a very slight enlargement of the lower gland will effectually compress the common biliary duct; he has seen its canal obliterated, from this cause, exactly at the point of contact with the swollen and indurated gland. He has, also, seen the cystic duct obliterated where it was in contact with the upper gland, in consequence of the enlarged and diseased condition of the latter; but he does not believe that this could have any influence in the production of jaundice.

Mr. T. does not deny the agency which biliary calculi — tumours of the pancreas, liver or spleen, or scirrhus pylorus may occasionally have in the production of the phenomena of jaundice, nor that, in some rare cases, the disease may have been excited simply by mental emotion; nor is he willing to place undue importance on the observations upon which his views of the most frequent cause of the disease are based. Should these, upon more ample investigation, be found to be correct, they will have an important influence upon the treatment of the disease.

According to Mr. T., the most successful plan of treatment in those cases of jaundice accompanied with pain, augmented upon pressure, of the right side of the abdomen, is by depletion by the lancet and leeches — active purgation — the daily use of the warm bath — and sudorifics, aided by low diet and perfect rest, in the commencement of the disease; followed by milder purgatives, and a small blister over the

region of the gall-bladder, kept open for a long time. Subsequently, a course of Cheltenham salts, or small doses of rhubarb and sal. polychrest, with gentle exercise, and frictions with camphorated liniment over the right hypochondrium are advisable: at the same time, it may be proper to allow a mild unirritating diet, in such quantities as shall improve the patient's strength. The disease may sometimes occur under circumstances that forbid depletion. This Mr. T. considers an unfortunate circumstance, as he has but little confidence in other modes of treatment.

In those cases in which the stools indicate the entire absence of bile from the intestines, Mr. T. considers the use of mercurials to be of doubtful propriety; but, when bile does pass into the duodenum, he admits that calomel may be useful, in conjunction with the remedies already detailed. Excepting in cases where there is pretty positive evidence of the existence of biliary calculi, which he believes to be less frequently a cause of jaundice than is generally imagined, he doubts the propriety of having recourse to opiates.

Whether the views of Mr. Twining in regard to the pathology of jaundice be or be not correct, must be determined by the result of future and more extended observations; they are sufficiently plausible and important, however, to demand the attention of the physician, and to influence him in his treatment of the disease. In respect to the plan of treatment recommended by Mr. T., we believe it will be found, with one exception only, to be, in a large number of cases, the only proper and successful one. The exception to which we allude, is the *indiscriminate* administration of active purgatives; jaundice is, not unfrequently, connected with more or less extensive inflammation of the stomach and small intestines, and in these cases, the employment of active purgatives to the extent recommended by Mr. T. would unquestionably be decidedly injurious.—C.]

The *gall-bladder* has its own diseases, which I do not stop to investigate, for they seldom become the objects of specific treatment. Sometimes it is found shrivelled up, and nearly empty; sometimes enormously distended; sometimes ulcerated; sometimes ruptured. Of these conditions, the distension of the gall-bladder is the only one that we can ever expect to recognize in the living body. The bag then projects beyond the edge of the liver, and is palpable externally, forming an elastic tumour in the right side. Authors lay down marks for distinguishing a distended gall-bladder from abscess of the liver, and from a hydatid cyst; but they are not much to be trusted in; nor is the precise diagnosis of any great moment. The practical rule seems to be that, when the swelling is adherent to the parietes of the abdomen, we may puncture it, whatever be its nature: but under no other circumstances.

I have already, incidentally, described most of the morbid states of the *spleen* which are susceptible of relief from medicine: especially the enlargement of that body constituting the *aque-cake* of the fens, and occurring in connexion with intermittent fever; and that other kind of enlargement which sometimes goes along with hæmatemesis and melæna. The spleen is liable to tubercles also; to deposits of other specific tumours, and of bone; and to softening of its substance. Sprinkled through it may not unfrequently be seen a number of yellowish or buff-coloured spots, which Dr. Kirkes believes, with good reason, to be little masses of fibrin, detached by the circulating blood from the interior of the heart, and arrested in the capillaries of this, and of some other organs, and especially of the kidneys. I mentioned these spots in a previous lecture.

The spleen is sometimes enlarged by the deposition within it of a whitish substance, albuminous in character, but called by some lardaceous, from its resemblance to hard bacon; by others waxy. The Malpighian bodies are first affected. This condition is the more interesting because it is apt to occur in the liver also, and in the kidneys. It is frequently found in more than one, or in all, of those organs at the same time. Hence we infer its origin from some constitutional cause. It is supposed to belong to the category of serofulous disorders: and it has often been met with in persons labouring under strumous caries of the bones.

Going along with certain other enlargements of the spleen (or of other glandular bodies belonging to the lymphatic system) there has been observed in the blood a greatly increased ratio of the white or colourless to the red corpuscles. Professor

Hughes Bennett, of Edinburgh, who was the first to draw attention to this remarkable state of the blood, has given to it, or to the disorder which it constitutes, the name of *Leucocythemia*, or white-cell blood. As yet this disorder possesses more of physiological than of practical interest; and I must limit myself to this passing notice of it.

The best remedy for the ague-eake is the remedy for intermittent fever, *quina*. Purgatives also have the effect of reducing hypertrophy of that curious organ. One caution enforced by Dr. Abercrombie is that, in splenic disease, mercury should be sedulously avoided, or rather such an employment of mercury as would risk tenderness of the gums. Dr. Robert Williams, of St. Thomas's Hospital, has stated, that having made many trials of the *bromide of potassium* as a remedy in various disorders, he had satisfied himself of its utility only in cases of diseased spleen. Of this I know nothing.

Again, it may seem a slight to the *pancreas* to pass it over without noticing the diseases to which it is subject. But really those diseases appear to be but few; and they do not signify their existence by any plain or intelligible signs. I have, nine or ten times perhaps in my life; met with carcinomatous deposits in the pancreas. In every instance the head of the gland, that extremity which lies next to the bowel, has been the exclusive or the principal seat of the disease. I have known this change in the pancreas to cause jaundice, by obstructing the bile-duets; I have known it in the same way to occasion very great enlargement of the liver itself; and I have known it to produce enormous and slowly fatal distension of the stomach by compressing the duodenum, and so preventing the free passage of the aliment through that gut. As to remedies for pancreatic diseases or disorders, I do not know of any.

Diseases of the *kidneys* — and disorders of their function — and alterations in the fluid they secrete — require more consideration. And I proceed at once to the subject of their *inflammation*; to *nephritis*; and it will be practically convenient to take *nephralgia*, or pain of the kidney, into the account at the same time. Nephralgia is commonly, but not always, produced by the transit of a urinary calculus from the pelvis of the kidney, through the ureter, towards the bladder. This constitutes what is called, in common parlance, *a fit of the gravel*. The symptoms are these: — pain, sometimes dull, but more frequently very severe, in the loins, usually on one side, and descending often along the track of the ureter of the same side; numbness of the corresponding thigh; in the male, retraction, and perhaps pain, of the testicle; a frequent desire to make water, which is generally high-coloured; nausea and vomiting.

If to these symptoms there be added pyrexia, we learn the important fact that inflammation is present: we have the symptoms of *acute nephritis*. The passage of gravel from the kidney sometimes does, and sometimes does not provoke inflammation of the gland. Nephritis is very seldom idiopathic. It may sometimes arise under the influence of cold; more frequently it is excited by calculous matter lodged in the kidney; by a blow or fall upon the loins; by the internal administration of cantharides, or of turpentine. It is to the presence of fever that we look, to establish the inflammatory character of the renal affection.

Nephralgia pains require to be distinguished on the one hand from rheumatic, and on the other from colic pains. In lumbago there is pain in the back, and it may or may not be attended with fever; but the pain usually affects both sides, and is aggravated by such movements of the body as call the muscles of the loins into action, particularly by stooping. It originates, frequently, in some strain or effort, of which the patient is made painfully conscious at the time. It is seldom accompanied by any notable trouble of the urinary functions. When rheumatic pain extends from the back into the thigh, it mostly follows the course of the great sciatic nerve, and is felt down the outer part of the limb; whereas the pain that accompanies nephritis or nephralgia shoots rather along the track of the anterior crural nerve. Lastly, lumbar pain, depending upon rheumatism, is not attended with nausea and vomiting.

The pain of colic is often associated with sickness and retching: and it may occupy those parts of the abdomen which correspond to the place of the ureters. The urinary functions are undisturbed; and this is a capital point of distinction. The

numbness of the thigh, and drawing up of the testicle, are sufficiently characteristic, when they happen; but they are frequently altogether absent.

Some years ago I was sent for by an exceedingly intelligent surgeon, who had been one of the house-surgeons at the Middlesex Hospital. I found him in bed. He told me he had pain in the abdomen. It had begun in the morning in the situation of the right kidney, and soon extended round to the right side of the abdomen and to the groin. Two days before, he had experienced a similar attack of pain in the renal region, stretching round into the hypogastrium. When I saw him he described the pain as lying more round the umbilicus than elsewhere; and he expressed a strong persuasion, from the feelings which attended it, that it would be removed by free action of the bowels. But he felt nausea; and had vomited some medicine which he had taken. He had no fever, no retraction of the testicle or numbness of the thigh, and the pain was not increased by pressure. Neither had there been any marked irritation of the bladder. He said, indeed, when I questioned him on that point, that he *thought* he had made water *rather* more frequently than usual the day before. I mention this case to show you the occasional obscurity of the symptoms. Here a well-instructed medical man believed that nephralgia, existing in his own person, was colic. To my judgment, however, it seemed most probable that a small calculus had been passing from his kidney towards, and perhaps into, his bladder. I may as well tell you the event of the case, which interested me a good deal; for it exhibits the train of symptoms that are apt to ensue after nephritic attacks; although in this instance they were but slightly pronounced. His bowels were well acted on by a purgative, and the next day he was free from pain, and apparently well.

Two days after this, he had more frequent calls to void urine than were usual with him, and having done so on one occasion, he presently felt the want again, and then passed a little blood. The urine had been of a clear amber colour throughout. At the expiration of two or three days more he called upon me to say that after making water he had perceived in the vessel a small crystallized mass, which he took out, supposing it to be (what it very much resembled) a fragment of sugar-candy. In fact he had been eating sugar-candy, and thought some portions of it had fallen down between his waistcoat and shirt, and afterwards into the chamber-pot. He had the curiosity, he said (some misgiving he must have had too, for I had told him my own opinion of the nature of his attack), to put a small crystal from this fragment into his mouth; and as it neither tasted sweet nor dissolved, he suspected it might be a urinary concretion, and brought it to me. And sure enough it was so; a piece of very pure oxalate of lime, which he had been fortunate enough thus to get rid of. It was a quarter of an inch in length, and less than one-eighth of an inch broad, consisting of an aggregation of small crystals. It was exactly similar in appearance and colour to a piece of brown sugar-candy of the same size. It would pass, longways, into a large crow-quill.

That it was oxalate of lime was proved in this manner. A little separate crystal was heated to redness on a piece of platinum foil, by means of a spirit-lamp and blow-pipe. By these means the oxalic acid was converted into carbonic acid, which was driven off by the strong heat; and quick-lime was left. This residue, moistened, and pressed into a powder on a piece of turmeric paper, gave the characteristic brown colour.

You see, then, that a nephritic affection may be mistaken for an attack of colic. In reference to practice, it would indeed be a mistake of no great importance, since the remedies that are proper in the one case are generally proper, or not improper, in the other. If the pain be attended with fever, antiphlogistic measures are alike indicated in each of the two diseases.

The numbness of the thigh, and the drawing up of the testicle, are analogous phenomena to the pain which affects the shoulders in hepatic disorders. Irritation of one extremity of a nerve, situate internally, and belonging to an organ which is not endowed with a high degree of sensibility, causes sympathetic sensations in the sentient extremities of other branches of the same nerve, or of communicating nerves.

And this sympathetic affection of distant parts is sometimes attended (as I formerly observed) not merely with pain, but with some degree of inflammation also. The testicle occasionally swells, and becomes tender, during a nephritic attack. On the other hand, as the nerves which communicate with those of the testicle or thigh may

or may not be implicated in the renal disorder, so we see how it happens that these curious symptoms, so instructive when they do occur, may frequently be wanting; as they were in the example I just now detailed to you.

When the symptoms I specified in the outset are attended with fever, we conclude that we have to deal with nephritis; and when inflammation of the kidney, however produced, lasts for a certain period, without abatement, *suppuration* is to be dreaded. Such suppuration is marked, sometimes, by the supervention of rigors, by throbbing perhaps, and it may be by a remission of the pain: but I believe it may take place without throwing out any such signals. Nay, I think it probable that inflammation, confined to the parenchymatous substance of the kidney, may arise, and run through all its stages, without denoting its presence or progress by any noticeable local signs; and that the sharp and peculiar symptoms ascribed by authors to acute nephritis, manifest themselves only when the investing membrane of the gland, or its pelvis and excretory tubes, are involved in the inflammatory process. However this may be, suppuration leads to ulceration, to the formation of renal fistulæ, to the establishment of a purulent discharge, and hectic fever; and finally, in most cases, to a fatal event; whether the inflammation was at first idiopathic, or dependent on a calculus.

I may illustrate these remarks, by stating the heads of a case which has occurred to me since this course of lectures began. I admitted Caroline Barnard, a married woman, forty years old, into the hospital, on the 18th of October. Among other things she complained of pain in the situation of the right kidney. She had been ill six weeks, and at the commencement of her illness her urine had been very turbid, as indeed it still was: and she had experienced much pain and difficulty in passing it, and after it had passed. From that time she had frequent nausea and retching, and occasional numbness of the right thigh. She had been losing flesh fast; and her pulse was frequent. There was some tenderness discoverable in the right renal region; and after a time a manifest fulness there, and hardness; and at length œdema of the integuments and *extreme* tenderness. She suffered also well-marked hectic fever, and had severe and repeated rigors. On the 4th of November, after a careful examination of the right loin, we satisfied ourselves of the presence of matter. I got Mr. Arnott, therefore, to see her, and to put a lancet into the abscess; and a large quantity of faint smelling pus came out. She was greatly relieved by the operation; and a purulent discharge, mixed with shreds of cellular membrane, came away in abundance for some days: but in time the discharge ceased, the swelling subsided, and the opening healed. We began to hope that it had been merely an abscess in the *neighbourhood* of the kidney, irritating it and affecting its functions. But in three weeks after the abscess was punctured, the swelling was found to have recurred; and she again began to suffer much. The tumour was again opened, and pus, of a more offensive character than before, evacuated. In the early part of December she sank.

We found the right kidney small, collapsed, and hollow; in some parts a mere flabby bag. On its posterior surface there was an opening, which formed a communication between the interior of the kidney and the abscess in the areolar tissue, which had pointed externally. The pelvis of the kidney was much dilated: and the substance of the gland destroyed to a considerable extent, by suppuration and ulceration. The ureter, where it left the pelvis of the kidney, was found to be impervious.

The other kidney was much enlarged; but of quite healthy and sound structure. That kind of compensation had occurred which I formerly mentioned as not unusual when, of double organs, one has been rendered incapable of its natural functions, and the other takes up its duty, and performs a two-fold amount of work. The organ of which the function is thus increased, becomes hypertrophied. This woman did not die because there was not urine enough secreted; but she sank under the wasting purulent drain, the irritation and pain she suffered, and the protracted hectic fever. In this instance the inflammation and suppuration occurred independently of the formation of calculous matter.

Sometimes the pus finds its way out of the body through the natural passages, and appears in the urine. This woman's urine was thought, by some of the pupils, to contain pus. It was quite thick, and of a yellowish colour. But heat rendered it transparent. You must not judge by a cursory look at the water. The effect of heat

proved that the yellow material was not pus; the impervious condition of the ureter showed afterwards that it could not have been.

When calculi exist in the kidney, they often betray their presence there, by causing *bloody urine*. But bloody urine may proceed from various causes; and in conformity with my usual custom, I shall by and by offer you some general remarks on hæmaturia, as one of the hæmorrhages.

I showed you, at our last meeting, that gall-stones might inhabit the gall-bladder in considerable numbers, and be quite harmless, unless they attempted to escape from their prison, through the very narrow channel of egress from it; and I intimated that the same observation was often applicable to urinary concretions. Renal calculi do indeed, in many cases, produce abiding uneasiness, or frequently recurring pain, in the situation of the affected kidney, bloody urine, and gastric disturbance; especially when the concretions are shaken or displaced by sudden jolts or jarring movements of the body; or when the system is deranged by intemperate habits. But in many other instances these calculi cause no pain or annoyance, so long as they remain in the kidney: although they inflict horrible suffering, in general, while, for the first time, they are forcing their way along the narrow ureter. A concretion cannot be formed in a moment; yet the attack of pain often comes on in a moment, without any previous warning. After a while it remits, perhaps as suddenly; the calculus having passed (it may be presumed) from the ureter into the bladder; and then indications, more or less palpable, usually begin to declare themselves of its presence in that receptacle. Moreover, it is not uncommon to find calculi in the kidney after death, of the existence of which there had been no symptom manifested during life.

The *treatment* of nephritis—or of the nephralgia calculosa, when accompanied by fever, or occurring in young, strong, and plethoric persons—is just such as would be proper in cases of severe colic, or enteritis: and therefore it is that any mistake between these disorders at the outset is not of so much practical consequence. The objects of treatment are, to arrest the inflammatory process; to quiet existing irritation; and to obviate any fresh causes of irritation. Venesection, therefore, in proportion to the strength of the patient and the violence of the symptoms, will sometimes be proper: and it will always be advisable to take away blood freely from the neighbourhood of the suffering part by cupping. Warm fomentations; the warm bath; the injection of warm water into the bowel; these are all expedients of which practical men acknowledge the value. The warm enemata not only clear out from the large intestines any irritating matters they might contain, but, from the proximity of the colon to the kidney, they have perhaps the effect of an internal fomentation. It is desirable also to get the bowels well acted upon by purgative medicines as soon as possible: the relief that follows free alvine discharges is often very marked. There is sometimes a difficulty, from the irritability of the stomach, in administering purgatives by the mouth. Calomel, however, will often be retained, when other substances are rejected. It is generally considered of importance to give those purgatives only which are not likely, after being absorbed into the blood, to irritate the urinary passages. On this account the *saline* purgatives ought to be avoided. Nothing is so good as castor oil, if the stomach will bear it; or infusion of senna, with manna, may be used; or, if the stomach be very queasy, *pills*, composed of cathartic extract and calomel.

When there is no fever, *i. e.* when the case is one of nephralgia, and a calculus is passing, after the intestinal canal has been cleared by a purgative, it will be necessary to give opium in full doses to allay the pain: and it may either be administered in the form of pill through the stomach; or introduced into the rectum.

When a person suffers what is called a fit of the gravel, the pain, I say, is at length very suddenly relieved, in general, in consequence of the calculus having emerged from the ureter and entered the bladder. We judge that this has taken place, first, by the cessation of the pain; and secondly, by the supervention, sooner or later, of symptoms indicative of stone in the bladder: *viz.*, a more than usually frequent inclination to make water; pain, referred to the extremity of the urethra, especially just after passing urine; and stoppages and renewals of the stream of water while the patient is endeavouring to void it.

The time which a calculus takes in travelling from the kidney to the bladder varies a good deal. The painful journey may be over in a few hours; or it may last two or

three days. More rarely the symptoms continue, with irregular intervals of comparative quiet, for weeks. And sometimes, notwithstanding the peculiar pain, which amounts to torment, all morbid symptoms cease, and yet no calculus has passed, apparently, into the bladder: none, *i. e.* of the symptoms of stone, ensue; no calculus is voided by the urethra; and none is found in the bladder when the patient at length dies.

What is the explanation of these circumstances? Why, as calculi have been discovered in such cases in the *kidney*, it has been supposed that a concretion may get into the very beginning of the ureter, where it is a little larger than elsewhere, and give rise to the peculiar symptoms, yet never pass fairly into that narrow tube; but at length fall back again into the pelvis of the kidney: when the symptoms cease.

FIG. 144.

Calculi of the kidney and ureter. From a specimen in Professor Willard Parker's collection.

But the same symptoms undoubtedly occur, occasionally, when there is no calculus at all. Sir B. Brodie has referred to this form of complaint. In people who live intemperate and luxurious lives, pain is apt to seize upon one renal region, and to extend round and downwards into the groin; and these symptoms will be followed by frequent, difficult, and painful micturition, the urine being unusually acid high-coloured, and sometimes turbid. The whole irritation appears to be produced by this unhealthy urine: at least the complaint vanishes after cupping the loins, purging, warm baths, and two or three full doses of colchicum given at short intervals. It is highly probable that small colourless particles of oxalate of lime give rise to these symptoms.

Sometimes the little stone becomes immovably wedged in the canal of the ureter. When it completely shuts the tube, the urine accumulates behind it, and that portion of the ureter dilates. The obstruction usually proves fatal, by its influence upon the functions of the kidney, and thereby upon the whole economy. But if the urine find a passage by the side of the impacted concretion, this danger is averted, or postponed.

When we have reason to believe, from the nature and course of the symptoms, that a calculus has come down from the kidney, and lodged in the bladder, then it becomes an object of deep interest to the practitioner, and of fearful importance to the patient, to try all means to bring about its expulsion before it grows too large to be voided. For grow it almost surely will, by the continual accretion of earthy matter upon its surface, if it remain long in the bladder. We know that it *may*, at first, be voided, provided the urethra be in a healthy and natural state; that whatever has passed through the ureter, may pass through the urethra also.

FIG. 145.

Dilatation of the ureter and pelvis of the kidney. From a specimen in Dr. Gross' cabinet.

The objects to be kept in view are these: first, to procure a plentiful secretion of bland urine, wherewith the bladder may become filled; secondly, by lulling the sensibility of the parts concerned, to prevent or lessen that spasmodic effort of the sphincter of the bladder, which the presence of the calculus is apt to provoke; and, thirdly, to ascertain that the channel of the urethra is open and unimpeded.

To effect the first of these purposes, the patient should be instructed to drink freely of diluent liquors; such as barley-water, or linseed-tea, in which may be mixed a small quantity of the sweet spirits of nitre. To fulfil the second, he should take a full dose of opium at bed-time. By these means the pain and irritation which may have been produced by the calculus, will be soothed; and the bladder will gradually fill. He should then make water, having first placed himself in such a position that the outlet of the bladder shall be at the lowest part of that receptacle. He may stand up, and lean forwards; or it may be well to make water while kneeling, in a warm bath. If these expedients are not presently successful, the urethra may be cautiously expanded, and habituated to the contact of a solid body, by the daily introduction of a full-sized bougie. Sometimes the calculus will follow the bougie, as it is withdrawn, through the urethra. In this way the patient will have a fair chance of getting rid of the stone. In this way a very near friend of my own, a physician now practising in this town, did expel a formidable, though not very large, piece of rough oxalate of lime several weeks after its entrance into the bladder. Out it came, at last, with a smart clink, which was music to his ear, against the chamber-pot. A gentleman was not long since sent up to me from Kent, by a former pupil of this College, with the following history. About a month before, he had been suddenly attacked with acute pain in the loins, extending forward into the left flank and pelvis; and with nausea and vomiting. For nearly ten days these symptoms continued to occur at intervals; then they ceased; and then he began to be troubled by a frequent and very urgent inclination to make water, and by pain after voiding it, just above the arch of the pubes. I gave him directions, in accordance with the plan just now mentioned; and wished him to allow some surgeon to explore the contents of his bladder. To this he would not, as yet, he said, consent. I saw him on the 2d of August. He returned into Kent the next day. On the 5th, while taking a walk, he was seized with a most imperative want to make water, but found that he could part with none. Concluding that a calculus had entered, and stopped up the urethra, he was proceeding homeward, but was soon constrained again to try to empty his bladder: and then he had the satisfaction of feeling, and seeing, a stone fly out with great force: but, as he had turned towards a hedge, he could not find it. From that moment he was quite easy.

When a calculus of a certain size has once traversed the tubes that lead respectively to and from the bladder, others sometimes follow it with more ease. I show you here a large concretion which was passed, or pissed if you will, by a patient of mine without his knowing it. He is subject to epilepsy, which is probably eccentric, and excited by renal disease. He is closely and anxiously watched by his wife. One day last year she noticed that the urine he had just voided was slightly tinged with blood: and she then found in the vessel this oblong stone, which is composed of lithic acid.

If the renal calculus, after it has reached the bladder, cannot be got rid of by the expedients I have been recommending, the question arises, whether medicine can do any further good, or whether the patient is to be delivered over to the surgeon.

Most of these small concretions admit of being mechanically crushed into smaller fragments, which are then readily washed out by the stream of urine. Larger stones are extracted entire, through incisions of the bladder. Yet there are many cases in which, for various reasons, surgery declines to attempt the removal of vesical calculi. Medicine still offers to these unfortunate patients the means of mitigating, at least, their sufferings. But it often can do more than this. It is very important for you to know that judicious medical treatment may retard or prevent, and that injudicious medical treatment may promote and hasten the enlargement of such calculi. Let us briefly consider the principles by which our judgment and our practice, in this serious matter, must be guided.

I have described a fit of the *gravel*. We say that a patient has the gravel when he passes concrete matter with his urine, whether in the form of powder, of grit or sand, or of more massive calculi. We do not apply that term to the cases in which

the urine is clear when recently voided, and warm ; but throws down a powdery sediment as it cools : which sediment redissolves if the urine be again artificially heated. Now besides the different forms which the gravel assumes, of powder, sand, and little stones, there are (as you may have guessed from certain terms that I have been obliged to employ) several *kinds* of gravel; differing, I mean, in their chemical composition. The main signs — the pain, the sickness, the affection of the testicle, the subsequent bladder symptoms, — are much the same, whatever be the nature of the solid matter that descends from the kidney, and lingers in the bladder. But other circumstances differ widely. The qualities of the water previously to the formation, and to the discharge, of the sabulous matter; the state of the system at large. And it is quite impossible to treat cases of calculus in the kidney, or of stone in the bladder, with propriety, or safety, without constant reference to the condition of the urine. The morbid states of that secretion are of the greatest interest. I cannot undertake to enter upon the subject in much detail. Yet some outline of it I must attempt, especially where it touches upon points of practice.

The office of the kidneys is simply excretory. Through them, and with the urine, are drained away many of the impurities, habitual or accidental, of the circulating blood; and any excess of its aqueous ingredient. It does not fall within my province to go into the chemical composition of the urine. That is fully taught in other lectures. It is enough to say that it is complex, and perpetually shifting. Everybody knows by his own observation that, compatibly with the most perfect health, the urine may vary considerably in its sensible qualities; in quantity for example, in colour, in its specific gravity. The average diurnal quantity is from thirty to forty ounces. If much liquid be drunk, more urine is secreted. If much water pass off by the skin, or through the bowels, less passes by the kidneys; and contrariwise. Its natural colour resembles that of wheat-straw, of amber, or of pale sherry. Its ordinary specific gravity lies between 1015 and 1025: that of distilled water being represented by 1000.

You know, probably, that the urine voided by a person in health always exhibits *acid properties*, always turns litmus paper red. Not that healthy urine contains a free acid; but only that certain of the alkaline and earthy bases are not exactly neutralized, but exist in the state of supersalts. Of these, most probably the acid phosphate of soda is the one which usually gives the acid reaction to the urine. You ought also to be aware of certain variations which take place, with much regularity, in the acidity of the urine. Want of attention to this point — or rather the want of knowledge on this point — has been a fertile source of mistakes. Dr. Benze Jones has ascertained that the urine is most strongly acid just before a meal, and that it gradually becomes less and less acid while digestion is going on. The acidity is least about three hours after breakfast, and five or six hours after dinner. The explanation of these changes is this. During digestion soda is set free in the stomach and finds its way into the blood, and so into the urine. The acidity of the gastric fluids, and the acidity of the urine, are in inverse proportion.

Modern chemistry teaches (I repeat) that the acid reaction of healthy urine is commonly due to the acid phosphate of soda. Dr. Prout ascribed it to a super-lithate of ammonia; but it seems doubtful whether a super-lithate of ammonia ever exists. Neutral lithate of ammonia, however, is very readily soluble in the saline urine. But whether out of the body, or within it, the lithate of ammonia will, of course, be decomposed if any free acid be present in the urine, for which ammonia has a stronger affinity than it has for the lithic acid; and the latter, being insoluble, will be slowly thrown down, in the form of a red or yellow sand: little crystals, in point of fact. they are; to the naked eye very often like, in shape, size, and colour, to particles of Cayenne pepper. Under the microscope the lithic acid is seen of various forms, according to the nature of the urine from which it is deposited. Of these forms the most marked are here exhibited. I show you also some of this red sand, collected by one of my out-patients at the hospital. He must have passed a peck of it while under my observation: and I am sorry (having lately lost sight of him) that I did not procure a large quantity for the museum.

Now this lithic (or uric) acid, or red sand, is liable to form in the kidney, if not in the bladder, and to concreate into calculi; and a calculus once formed, or, indeed, any solid substance, will constitute a nucleus, upon and around which a

FIG. 147.

Fan-shaped aggregates of tubular crystals of uric acid, rather less often met with in urinary deposits.

further and repeated incrustation of a similar nature is almost sure to take place. You will at once perceive the importance of doing nothing to aggravate this disposition to deposit lithic acid; but of trying to prevent or stop it. If there be symptoms of stone in the kidney, or in the bladder, and we have reason to believe that it con-

Uric acid.

sists of lithic acid, there are medicines which would tend to make matters worse, and there are others of which the effect would be to correct the lithic acid *diathesis*, as it is called. But how are we to know whether the presumed calculus be of that kind or not? or, rather, how are we to know that the lithic diathesis exists? Why, we learn that it exists by noticing the habitual qualities of the urine, and the habitual state of the patient's general health.

The urine of persons who have the lithic diathesis is bright, of a dark golden or coppery colour, like brown sherry. Sometimes it feels slightly pungent in the urethra as it is passing. It is more acid than the urine of health, and gives to blue litmus paper a deeper shade of red. Commonly it contains more than the usual amount of urea, and has a high specific gravity. It is apt, too, to fall below the average quantity.

The lithic acid is not often thrown down before the urine is voided. When it is, it appears in separate crystals, in the shape of fine sand; or in coarser roundish grains, which are in fact minute concretions of crystals.

You must not confound this crystallized lithic acid gravel with those amorphous powdery deposits which are much more common and more copious, and which consist

of lithic acid in combination with ammonia, lime, magnesia, or soda. They are generally spoken of as lithate (or urate) of *ammonia*, but are chiefly composed, I believe, of lithate of soda. The colour of these lithates is sometimes pale, and almost white; more often of a yellowish brown; or red, like brick-dust; or occasionally of a deep purple, or almost crimson tint. They are never deposited till the urine has cooled. People are liable to be frightened by their appearance; apprehending that they may harden into a stone in the bladder. But you may always relieve their anxiety by stating that these sediments are never substantially present in urine at the temperature of the body. You may show that they presently dissolve and vanish, as the urine is again warmed. The lithic sand does not so disappear. The lithates are apt to stain the surface of the vessel, and they render the whole of the urine turbid when it is shaken: whereas the lithic sand rolls over at the bottom when the vessel is slowly tilted, and does not trouble the general transparency of the stirred water.

These, and all other urinary deposits, are in most instances discriminated more easily, more quickly, and more surely, by means of the microscope, than in any other way; and you may now carry in your waistcoat pocket a microscope which is practically sufficient for this purpose, and perfectly simple in its use. A single glance at a drop of urine containing the sediment will reveal its character with more accuracy than could be attained by a long and laborious chemical analysis. The lithate of soda appears in molecular granules, which are often arranged in little tufts, and look like fragments of moss. True lithate of ammonia sometimes presents itself in a rounded form, with one or more little projecting spikes—resembling a minute thorn apple.

FIG. 151.

Bi-urate of Ammonia.

FIG. 150.

Urate of Soda deposited from Urine.

FIG. 152.

Nitrate of urea, separated from very concentrated human urine by nitric acid.

Now the lithates of which I have been speaking do sometimes — do not seldom indeed — show themselves in urine which deposits the lithic acid crystals also; and you must then warm the urine, and disperse the lithates, before you can obtain a clear view of those crystals. But in such cases the nature of the disorder, and its proper treatment, are both determined by the presence of the lithic acid; and the concomitant lithates are of secondary importance. I shall have something further to say of them, however, presently.

The presence of the so-called lithic diathesis is likewise accompanied, and so far

denoted, by a tendency to feverish and inflammatory complaints. The patients are troubled with transient twinging pains in their limbs, and many of them are subject to gout or rheumatism. They are mostly also indolent and luxurious, or intemperate in their mode of life. Adults are peculiarly obnoxious to this condition of the system after the age of forty. But children, up to the period of puberty, are very liable to have lithic acid gravel: and in this early period of life such deposits indicate, according to Dr. Owen Rees, a tendency to grave disease.

Whenever a paroxysm of nephritic pain befalls a person whose time of life, whose habits, the character of whose health, and the habitual qualities of whose urine, are such as I have been describing, you may conclude that the concretion which has occasioned the symptoms is of the lithic acid kind: and you may expect that such attacks will recur; for it is observed of these lithic acid renal calculi, that they are generally numerous in the same individual. I speak of the *habitual*—or of the *frequently recurring*—qualities of the urine: for a deposit of lithic acid gravel, as well as of superabundant lithates, may occur to the healthiest individual, under accidental and transient disturbing causes. Many persons will tell you that their water presents a red sand whenever they have a cold. Febrile and inflammatory ailments may produce the sediment: even too full a meal: or exercise taken immediately after a full meal. In all such cases it seems probable that the customary evolution of free acid through the skin is somehow prevented: in consequence either of a check given to the perspiration, or of imperfect assimilation of the food. The free acid thus diverted from its natural emunctory—or some acid introduced from without, or generated within the system—is determined to the urine, and precipitates the lithic.

Dr. Benec Jones, in a paper which you may read in the *Philosophical Transactions* for 1845, has pointed out one way in which an excess of free acid sometimes comes to the urine. From disorder of the stomach an excessive quantity of free hydrochloric acid is there secreted, and remains there during the whole process of digestion. If urine be at that time passed, it may be found alkaline from fixed alkali; and so it continues until the contents of the stomach are absorbed, when the free acid which was in the stomach passes off in the urine, making it intensely acid, and precipitating lithic acid, or the lithates, according to the quantity of free acid, and the length of time during which the urine (after being secreted by the kidneys) is submitted to its action.

Now the formation of lithic acid in the urine attests its over-acid condition, and both the one and the other may be controlled by the exhibition of alkaline remedies. You will find that free livers use alkalies to neutralize the excess of acid which results from their intemperate habits; the carbonate of soda, or of potass. They do this, without any reference to the appearance of their urine, to prevent or appease the uneasy feelings produced by a debauch. But it is of importance to be aware that one of these alkalies is preferable, for the purpose of obviating the lithic acid deposits, to the other. Soda will sometimes combine with the lithic acid, and form an insoluble salt, as hard, and as pernicious, when deposited around a nucleus, as the lithic acid itself. With potass there is no such danger. If it should combine with the lithic acid, the resulting salt is perfectly soluble, and will pass away dissolved, in the urine. Magnesia is also a good medicine in such cases; but it has this disadvantage, as I showed you indeed before, that it is apt, when taken habitually, to cause *intestinal* concretions; and these may be as dangerous as the urinary ones. One of the best modes of giving the bicarbonate of potass is in the common saline draught. The salts of vegetable acids are converted, *in transitu*, into carbonates. The change appears to take place, not in the stomach, but in the blood; and to be caused by the action of oxygen. The remedial properties of the bicarbonate, thus administered, are the same with those of the pure alkali, while it is much less likely to derange or disagree with the stomach. The phosphate of soda is a powerful solvent of lithic acid; and this salt has been suggested by Dr. Golding Bird as a suitable drug in these cases. It tastes, in a dilute solution, somewhat like common salt; and it may conveniently be taken in scruple or half-drachm doses, dissolved in broth, or gruel. The Vichy water furnishes another efficacious alkaline remedy, which may be used as a beverage. Of course the mode of living ought to be changed when the lithic diathesis prevails; the patients should dine moderately and plainly, eating of one dish, and avoiding acids and all articles of diet likely to generate acid in the stomach; saccharine sub-

stances therefore, starch in all its forms, and fermented liquors. But, as I remarked in a former lecture, they will not, if they can help it, give up their accustomed indulgences: and they attempt, and we attempt, but the attempt is often made in vain, to remedy disorders, which might with ease and certainty have been prevented.

You must take care not to give these alkaline remedies too long; nor in too great quantity. You must not push them to such an extent as entirely to destroy the acidity of the urine: for if you do, your patient is exposed to the same danger as before, but from an opposite cause. A *white* sand or gravel will be apt to form in the alkaline or neutral urine: and this will collect itself, by the force of aggregation, around any existing calculus, or foreign substance. The white deposits consist mainly of the triple phosphate of ammonia and magnesia, mixed with amorphous phosphate of lime; and if you examine collections of urinary calculi, you will find that they are sometimes made up of concentric layers; and one layer may be composed of lithic acid, and the next of the mixed phosphates; and so on, as the condition of the urine has alternated. You must test the urine therefore, and see that it still reddens litmus, though perhaps faintly. Indeed it may do so, without containing acid enough to dissolve all the earthy phosphates, if they are present in excess; so that urine which only slightly reddens litmus paper may nevertheless be capable of sometimes depositing the earthy phosphates. The saline draught has always a tendency to make the urine alkaline; and thus it is, probably, that it proves of use in febrile disorders; but it may become a poison to those whose urine is already alkaline. Colchicum has a similar tendency to diminish the acid reaction of the urine. So has mercury. And I may tell you — speaking generally of morbid states of the urine — that it is much more easy to correct too great acidity than to rectify the opposite condition. We can almost always make acid urine neutral or alkaline: but to render alkaline urine acid is often beyond our power.

In truth, the administration of alkaline drugs, which, by clearing the urine of superfluous acid, staves off a present danger, does nothing towards redressing that state of the system from which the excess of acid, and the danger, proceed. Alkalies operate upon an effect, but leave its cause untouched. A long continuance of them may even tend, apart from their immediate effects upon the urine, to lower the general tone of the body, to render the muscles flabby and weak, and the complexion pale. To cure the morbid disposition the patient's regimen must be prescribed. His diet must be regulated, as I have explained already: and it is scarcely less important to attend to the functions of the *skin*, in persons having the lithic acid diathesis, than to the functions of the stomach. The warm bath is often an excellent adjuvant in their treatment: or, where it can be borne, the daily use of the cold or tepid sponging bath, with subsequent friction by the flesh brush, or hair-glove. In cold weather warm clothing must be enjoined; and the avoidance, in all weathers, of such exposure to cold as might suppress or materially lessen the amount of healthy perspiration.

Active exercise in the open air, furthering the removal of acids through the skin, and of carbonic acid through the lungs, is also of great importance: and it may be requisite to promote the healthy action of the liver and bowels by mild aperients containing a small proportion of mercury.

A word or two more about the deposit of *lithates* in the urine. I have already remarked upon the variety in their colour. When this does not result from the presence in the water of some accidental colouring matter, useful inferences may occasionally be drawn from the peculiar tint of the sediment. Those deposits which have a tawny or reddish yellow, or what Dr. Owen Rees describes as a nut-brown hue, are the most innocent. They are frequently the effect of mere indigestion, of a common cold, or of some other slight and transient disturbing influence. The white lithates are of more equivocal import. They seem to precede sometimes, or to accompany, the excretion of a small amount of sugar through the kidneys. They should suggest vigilant care and inquiry. Those which present a pink or brick-dust colour are mostly associated with febrile states of the body, and are common in acute rheumatism. When such sediments are habitual, and without fever, they are often connected with organic visceral mischief. The purplish or crimson deposits were believed by Dr. Golding Bird to be "almost pathognomonic of disease in the organs in which portal blood circulates."

The quantity of lithates contained in healthy urine varies continually and considerably: it is generally the greatest a few hours after a meal. The precipitation of these natural constituents of the urine depends upon several distinct causes.

Do not fall into the common and not unnatural mistake of supposing that urine which throws down the lithates, is therefore and necessarily over acid urine. It may be so: but very often it is not so. The less acid the urine is, the more of the lithates is it capable of holding in solution, and so concealing. If the urine be very full of them, and at the same time be feebly acid or neutral, or alkaline, there may be no precipitate. Again, the urine may be very acid, yet if it contain but a scanty amount of lithates, none of those lithates may be rendered visible. The most favourable condition for their sinking down is when there is present a slight excess of their average quantity, and also a slight excess of acid in the urine.

Two other circumstances must always be taken into account; viz., the absolute quantity of the urine itself, and its temperature.

The amount of lithates being the same, they will be less readily retained in solution as the quantity of their aqueous menstruum diminishes: and the colder that menstruum becomes, the less of the lithates will it be able to hold dissolved. Hence we see how a slight cold, which implies generally some check to the perspiration, and a scantier secretion of urine, is apt to be accompanied with a deposit of the lithates. The appearance will be augmented, if the temperature of the atmosphere be low. It occurs in frosty weather often, when there is no appreciable derangement of the health whatever. It is clear that these are not cases for active alkaline remedies. All that they require is warmth to the surface, diaphoretics perhaps, to preserve the balance between the skin and the kidneys, or gentle diuretics, a few grains of nitre for example, to increase the quantity of urine excreted.

Bear in mind, then, that the two conditions, of increased acidity of the urine, and of an excess of the lithates or of lithic acid, may concur; but they require to be distinguished. There is no necessity for their coincidence. They are constantly met with separate and distinct the one from the other. In gout, in indigestion, and in some other disorders, there appears to be an absolute increase in the amount of uric acid or of urate of soda; and to this state of the system the term *lithic diathesis* ought, in strict propriety, to be confined.

You will have gathered, from what I have already said, that there is a morbid condition of the body, the opposite of that which is characterized by a prevalent deposit of the lithic acid: a state in which a readiness is manifested to throw down *white gravel*, and to which, by high authority, the title of the *phosphatic diathesis* has been annexed. But this phrase also will be apt to mislead you, unless you are made aware of what it means, and of what it does not mean. It does not imply, then, any excess of the phosphates in the urine: while it does signify their frequent appearance in that secretion under a substantial and visible form; in one word, their deposit. And as the deposit of the lithates depends often upon a superabundance of acid in the urine, so that of the phosphates is determined by the opposite condition, by a deficiency of acid, by alkaliescence of the urine. And even with respect to this alkaliescence, some further distinction is needed. There are two kinds of alkaliescence:—alkaliescence from the presence of a fixed alkali,—the carbonate of potass, or the carbonate of soda, or the alkaline phosphate of soda; and alkaliescence from the presence of the volatile alkali,—the carbonate of ammonia. Urine alkaline from this last cause,—well known as ammoniacal urine,—especially indicates the phosphatic diathesis of Dr. Prout.

Earthy phosphates are very insoluble in alkaline fluids, and very soluble in dilute acids. The minutest trace of these phosphates will be made visible if the urine become any how alkaline; and a very great excess of them will be hidden from the eye in urine that is healthily acid, by their ready solution therein.

Here then, as before, the old rule, “*de non apparentibus et de non existentibus*,” would be fallacious. The non-appearance of the phosphatic deposits in the urine has been mistaken for their absence; and their appearance has been wrongly assumed to denote their presence in excess. All this has been clearly laid down by Dr. Bence Jones.

The white gravel which is deposited in that condition of the system to which Dr. Prout has applied the term phosphatic diathesis, but which is better characterized by the presence of ammoniacal urine, is composed of minute shining prismatic crystals

of a triple salt, the phosphate of ammonia and magnesia. The way in which this is formed, according to Dr. Prout, is as follows. Healthy urine contains the phosphate of magnesia, which is very soluble, and therefore is dissolved, in that fluid. But, under certain circumstances, the urea of the urine becomes decomposed in the kid-

neys, or in the bladder, and ammonia is extricated, which combines with the phosphate of magnesia, and forms a triple salt, insoluble in the slightly alkaline urine. Almost always with the triple phosphate just mentioned, there is also an admixture of phosphate of lime in the shape of an exceedingly fine amorphous precipitate.

The tendency to deposit the mixed phosphates, with a predominance of the triple phosphate, is accompanied frequently with local disease in some part of the urinary apparatus, especially in the bladder and prostate gland. It is no unusual consequence of injuries of the back, — or rather of some morbid state of the spinal cord. The immediate link in the chain of connexion between the cord and the urine, in these cases, seems commonly to be a chronic inflammatory condition of the mucous membrane of the bladder; the decomposition of urea being effected by the altered mucus. The urine is sometimes pale, sometimes of an orange or copper colour. It always contains crystals of phosphate of ammonia and magnesia, and in many or most cases pus globules also are made visible by the microscope. Upon its surface a sort of film is often formed, exhibiting, as you look at it in different lights, the various colours of the rainbow; an iridescent pellicle. This has been found to consist of the triple phosphate, and sometimes of the phosphate of lime. If you skim the pellicle off, by placing a bit of paper under it, and then suffer the paper to dry, you may distinctly see the little crystals. Urine of this kind speedily grows putrid and highly offensive, and has a strong ammoniacal smell. It turns red litmus paper blue, but as the paper dries the red colour reappears. The alkalescence is from the carbonate of ammonia.

This, then, is the most usual form of the phosphatic deposit: the urine becoming

alkaline after it is secreted, and precipitating the earthy phosphates. But I have stated that the urine may be alkalescent from a fixed alkali; and then, no ammonia being present, the triple phosphate of ammonia and magnesia is not thrown down, but the phosphate of lime alone falls as a fine white powder, or forms a scum of the most iridescent appearance on the surface. In these cases the urine is secreted alkaline, and frequently an over-acid state alternates with this alkalescence. The urine itself is pale, copious, slightly turbid or opaline, of a low specific gravity, and it does not smell like healthy urine: occasionally it has somewhat the faint odour of weak broth. The white sand is deposited as the water cools, and sometimes even while it is yet warm, and in the bladder; so that the last portion of the issuing stream looks milky. By such urine, reddened litmus paper is made permanently blue. No prismatic crystals of the triple phosphate can be seen in it, nor any pus globules detected; although mucus, and oxalate of lime octohedra, are often present; mixed with an amorphous, or more rarely a crystalline deposit of phosphate of lime.

There are conditions of health in which the absolute amount of earthy and alkaline phosphates together is increased, and to these conditions the term phosphatic diathesis is appropriate. The amount of earthy phosphate alone depends so much upon the quantity of lime or magnesia present in the urine, that the excess of that salt only might rather be considered to denote an *earthy* diathesis: while the epithet "phosphatic" might be limited to that in which there is an increase of the phosphoric acid (combined always with alkaline or earthy matter) in the urine. The total amount of the phosphates in the urine never displays itself to the eye, for the phosphates of soda, which are the most abundant of them, are held in solution whether the urine be acid or alkaline.

Bear in mind that an excess of the lithates, and an excess of the phosphates, are perhaps both of them rare; while variations in the acidity and alkalescence of the urine are certainly exceedingly common. Even during perfect health the urine not unfrequently becomes alkaline during the process of digestion; the alkalescence being then always due to fixed alkali. Pink litmus paper dipped into it becomes blue, and remains so upon drying.

That the prevalence of ammoniacal urine, — associated as it commonly is with disease of the mucous membrane of the urinary passages, which disease is often itself the result of some profounder fault in the nervous system, — that such urine, when constant or frequent, denotes a very unsafe and unpromising condition of the body, you will readily believe.

Moreover it is a fact of great practical importance that — apart from any such local damage — the tendency to alkalescence of the urine from fixed alkali, and therefore to phosphatic deposits, goes along with general debility, and signifies that the health has fallen below its natural standard. Persons who are jaded and spent through over-much toil, whose vital energies have been depressed by mental anxiety, by insufficient nourishment, or by sensual excesses, are very apt to pass water that is alkalescent, or but faintly acid, and to exhibit in their urine the tokens of the so-called phosphatic diathesis. They are, for the most part, cachectic, sallow, languid, spiritless, exhausted.

Anything which tends further to depress the powers of the system will aggravate this alkalescent disposition. When you find that your patient passes urine such as I have been last describing, which does not redden litmus paper, but on the contrary turns litmus paper that has been reddened by a weak acid, blue again, or even in some cases is alkaline enough to make turmeric paper brown — in such cases you must cautiously abstain from all drugs or measures that are calculated to lower the vital powers; from saline draughts, and alkalies of every kind; from mercury and colchicum; from bleeding; and even from active purgation; or you will add to the patient's dangerous weakness; and promote the more abundant deposit of the phosphates.¹

¹ Dr. Owen Rees believes that in cases of alkaline urine, associated with a morbid condition of the mucous membrane of the bladder, the urine, as secreted by the kidney, is over-acid, and tends to keep up, or to aggravate that morbid condition; which, in its turn, renders the urine contained in the bladder alkaline. He counsels, therefore, an alkaline treatment in such cases, and indeed in all inflamed states of the urinary mucous surfaces. In this way the urine, as first secreted, may be made alkaline, and then the inflamed mucous surfaces, no longer irritated by an acid fluid, recover themselves and cease to pour out their alkaline liquor; till at length the healthy and acid secretion from the kidney is voided through the urethra.

The soundness of the theory can be tested only by the success of the practice. I can say nothing on the subject from my own experience.

But you may do more than abstain from what is hurtful: you may counteract the alkaliescent tendency by a generous diet and by the exhibition of tonic medicines; bark, wine, and acids: the muriatic acid, or the nitric, or both together, may be given in such cases before meals with vast advantage sometimes. Opium is also a remedy to be employed in this form of disease. No single drug probably has so much power in rendering alkaline urine acid, as opium. And it is indicated for other reasons; it composes the nervous anxiety to which these patients are mostly a prey. Mental relaxation—freedom from care—the relinquishment of all exhausting habits and pursuits—these too are points of vast importance, whenever they are attainable.

There is yet another diathesis sufficiently common and important to claim your best attention. I mean the *oxalic*: in which there is a tendency to the formation, in the kidney, of the oxalate of lime, or *mulberry calculus*; an epithet derived from the occasional resemblance of the concretion to that fruit, in respect of colour and inequality of surface. This diathesis is not so obvious as the other two, but it is no less real. By the use of the microscope we find that it is nearly as frequent as that in which the lithic acid, or the lithates, are precipitated, and far more common than that which is marked by deposits of the phosphates.

FIG. 161.—The octohedral crystals of oxalate of lime, as seen when allowed to dry.

FIG. 162, 163.—Dumb-bell crystals of oxalate of lime from urine.

The urine differs much in its sensible qualities from that of both the preceding varieties. Unlike the urine of the phosphatic character, it is often bright and clear; unlike that of the lithic, it is remarkably free from sediment. The mulberry calculus is solitary also; or recurs at long intervals; and is chiefly met with during the prime of life. In both these particulars the contrast with the habitudes of lithic acid concretions is striking.

The persons who manifest this disposition are usually dyspeptic; sometimes very much so; sometimes very slightly. They are uneasy during the assimilation of their meals; suffer flatulence when the stomach is empty; prefer vegetable diet to animal; are fond of sweets, especially of sugar. They are liable to boils and carbuncles, and to scaly cutaneous eruptions. According to their original temperament, they are nervous and irritable, or dejected and desponding in mind. A nephritic attack relieves them from all this discomfort for years perhaps. When the oxalic diathesis is strongly marked, the skin, Dr. Prout says, "is apt to assume an unnatural appearance difficult to describe, but the colour of which may be said to vary from dull greenish yellow in the sanguine, to dark olive or livid in the melancholic temperament." Young and old appear to be equally liable to this diathesis. In scrofulous children it is constantly to be observed. In fact, most of the residents in large towns who suffer even the slightest dyspeptic symptoms will be found to pass more or less oxalate of lime in their urine.

The formation of the oxalate of lime within the body depends, according to Dr. Prout, either upon the non-assimilation of oxalic acid taken with the food, or upon the mal-assimilation of saccharine aliments. Hence, as a general rule, both curative and prophylactic, *sugar* and other saccharine substances should be rigidly excluded from the diet of these patients. They should avoid, also, all kinds of fermented liquor. The young stalks of the *rhubarb*-plant, which of late years have come into such general use in this country for tarts in the spring; and *sorrel*, of which our neighbours, the French, consume a good deal in salads, and in other ways; both contain oxalic acid: and *hard water* contains lime. Dyspeptic persons who drink such water, and eat such articles of food, and are thus daily introducing, without suspecting it, the constituent ingredients of the mulberry calculus, are very likely indeed to incur the pain, and the exceeding peril, of a renal concretion of that kind. You must see, therefore, the great importance of detecting the oxalic diathesis; and of forbidding, to those who have it, all such viands as contain the oxalic acid, and of recommending them to use pure water, even distilled water, for drinking. Animal food, and the stronger farinaceous matters, and weak brandy-and-water rather than beer or wine, are best for them.

Professor Liebig first pointed out the close relation of uric acid to urea and oxalate of lime. He showed how these last two may be formed from uric acid in the laboratory: and some later experiments on animals by Woehler, have proved that they actually are so formed, within the body.

Agreeing with Dr. Prout, that the mulberry *calculus* is not of very frequent occurrence—Dr. Golding Bird first made us acquainted with the fact that small octahedral crystals of the oxalate of lime are extremely common: although from their transparency, and from their having nearly the same refractive power, and nearly the same specific gravity with the urine in which they exist, they do not frequently disclose themselves to the naked eye, nor sink down in manifest deposit. They are made plainly visible by the microscope: though sometimes its highest powers may be required, and it may be necessary to leave the urine for twelve hours after it has been voided, in order to allow the oxalate to crystallize out. From the quantity of epithelium which usually accompanies the crystals, a degree of cloudiness of the urine is frequently perceptible.

The same writer states also that the persons whose urine is thus charged with crystals of oxalate of lime are, for the most part, exceedingly sensitive and irritable, hypochondriacally apprehensive of impending evil, full of gloomy fears concerning their bodily and mental powers, dyspeptic, weak, and usually emaciated. But this description applies to extreme cases only. In both adults and children, slight cases present no symptom whatever; and it is only by the microscope that they can be recognised.

With respect to direct remedies for this diathesis, Dr. Prout tells us that he has seen more benefit derived from the mineral acids, alone or combined with tonics, than from any other. And certainly I have myself seen, in numberless instances, and at first not without marvelling, a vast improvement in the condition and feelings of such patients follow speedily upon the administering of the nitro-muriatic acid, in moderate doses, about an hour before their several meals. Preparations of iron also

are advisable if the patient be anæmic : and besides the prescription of these drugs, the avoidance of any excessive addition to study, or to business and its cares, and (as far as may be) of mental anxiety and worry, should be at the same time enjoined. The effects of the acids require to be watched : and when they begin to produce a deposit of the lithates, or of lithic acid, their use must be suspended. Dr. Prout was in the habit of recommending for patients who happened to live at a distance, the muriatic, or nitro-muriatic acid, till the lithates, or the lithic acid, began to appear in the urine ; or for a *month*. "By adopting," he says, "such a course of acids three or four times in the year, and by a carefully-regulated diet, I have seen the diathesis gradually subdued, and at length removed altogether." Dr. Bird also testifies to the efficacy of similar measures.

There is another diathesis still, named after the *cystic oxide*, a substance which is chiefly remarkable for the quantity of sulphur which it contains. This is but rarely met with ; yet it is worth mentioning.

These observations will serve, I hope, in some degree, as landmarks, to guide your treatment of patients labouring under renal or vesical calculi, or presenting symptoms such as warrant the apprehension that disorders so fearful may occur. It is impossible for me to do full justice to this important subject in these lectures ; and I must refer you, for more minute information respecting it, to Dr. Prout's invaluable volume ; to Sir Benjamin Brodie's most instructive book on the *Diseases of the Urinary Organs* ; to the excellent work of Dr. Golding Bird, on *Urinary Deposits* ; to the published *Lectures* of Dr. Owen Rees ; and to various papers in the *Lancet*, and in the *Philosophical Transactions*, — full of original research and interest, — by Dr. Benec Jones.

LECTURE LXXVII.

Suppression of Urine. Diabetes; Qualities of the Urine; Symptoms; Anatomical Appearances; General Pathology of the Disease. Treatment. Diuresis.

SYSTEMATIC writers have adopted the term *Ischuria*, to express that condition in which no urine is voided. It includes, therefore, those cases in which no urine is secreted; and those in which, although secreted, it is not discharged from the body. Now these two conditions are exceedingly different from each other in most respects; and I shall prefer making use of the two plain English names, *suppression* of urine, and *retention* of urine. Even these terms are sometimes confounded with each other. In *suppression*, the secretion is suspended: in *retention* it may be as active as ever. Retention of urine is a surgical complaint; involving points of great practical interest. Suppression belongs the physician; and the technical term for it is *Ischuria renalis*. It is sometimes spoken of as paralysis of the kidney; a phrase to which I object, because I think palsy is a word which ought to be restricted to a loss of power over the muscular fibre.

The affection usually occurs in persons who are advanced in life, and inclined to corpulency. Why it should be so I cannot tell you, but such is the fact, as stated by most observers. Sir Henry Hallford has related one of five instances of this disease that he had met with in the course of seven-and-twenty years. He says it was an exact copy of all the others that had fallen under his notice: and as his account of the general course of the symptoms coincides with the statements of other writers, I may give you his narrative, in lieu of a formal description.

"A very corpulent, robust farmer, of about 55 years of age, was seized with a rigor, which induced him to send for his apothecary. He had not made water, it appeared, for 24 hours. But there was no pain, no sense of weight in the loins, no distension in any part of the abdomen:—and therefore no alarm was taken till the following morning, when it was thought proper to ascertain whether there was any water in the bladder, by the introduction of the catheter: and none was found. I was then called (says Sir Henry), and another inquiry was made, some few hours afterwards, by one of the most experienced surgeons in London, whether the bladder contained any urine or not: when it appeared clearly that there was none. The patient sat up in bed, and conversed as usual, complaining of some nausea; but of nothing material in his own view: and I remember that his friends expressed their surprise that so much importance should be attached to so little apparent illness. The patient's pulse was somewhat slower than usual; and sometimes he was heavy and oppressed."

"I ventured to state (continues the author) that if we should not succeed in making the kidneys act, the patient would soon become comatose, and would probably die the following night: for this was the course of the malady in every other instance that I had seen. It happened so: he died in thirty hours after this, in a state of stupefaction."

This is the curious and important point in the history of such cases. If no urine be separated from the blood, coma soon supervenes, and death. It is believed that these consequences result from the detention of *urea* in the system. Urea is a mere excrement, which, in health, is removed from the blood by the kidneys, as fast as it enters that fluid. When it is not so carried off, it accumulates in the blood, circulates with it to every part of the body, and acts as a poison, especially upon the brain. To render it thus poisonous, however, its decomposition in the blood appears to be requisite, as I shall explain more fully in the next lecture. This is one of numerous instances, showing that the carrying fluid of the body may become the vehicle of disease and death, if it be not duly purged of deleterious matters which pertain to the unceasing processes of organic life. If *carbonic acid* be not extricated by the lungs, the animal functions are as certainly and almost as speedily extinguished by that gas, as the flame of a taper might be. And we have recently seen that when the outlet

from the liver is shut up, when the blood is not purified from the excrementitious *bile*, the powers of animal life are weakened, and sometimes utterly and rapidly destroyed.

Suppression of urine, for a considerable time, is not, however, necessarily and universally fatal. Patients labouring under the epidemic cholera would secrete not a drop of water for some days; and yet recover. It was remarkable how entirely free such patients were from any approach towards coma. Was the urea here drained off from the blood in the enormous and unnatural flux from the stomach and bowels? I think it probably was: but chemical search has not detected that substance in the fluids so effused. Schmidt thinks indeed that it would be found, but for its rapid decomposition into carbonate of ammonia. There are, however, some very singular instances on record, of persons who have passed days and even weeks without secreting urine; and without showing any other indication of impaired health. What degree of credit such narratives deserve I do not know; but assuming that there was neither fraud nor mistake, it may be suspected that either the natural secretion was compensated by some vicarious or supplemental discharge; or that a *small* quantity of urine was actually separated by the kidneys. "If any water, however small the quantity (remarks Sir Henry Hallford), had been made in these cases, I should have thought it possible that the patient might have recovered: for it has often surprised me to observe how small has been the measure of that excrementitious fluid which the frame has sometimes thrown off, and yet preserved itself harmless. But the cessation of the excretion *altogether* is universally a fatal symptom *in my experience*, being followed by oppression on the brain." The same eminent physician states that in three of his five cases there was observed a remarkably strong urinous smell, in the perspiration, for twenty-four hours before death. This I believe is of common occurrence in such cases. Other patients have vomited, or passed by the bowels, watery matters possessing some of the sensible qualities of urine: and a urinous fluid is said to have been found in the ventricles of the brain in some of the fatal cases.

I have spoken of suppression of urine as a malady, though it probably is never anything more than a symptom. Yet it is one of those symptoms which from our uncertainty respecting their origin and determining cause, we are obliged to treat, and to study, as if they were substantive diseases. In the only well marked instance that I have seen of suppression of urine coming on in an apparently healthy person, some blood had appeared in the urine for a day or two before the secretion was totally suspended; and the kidneys were found gorged with blood. Extreme congestion, or inflammation, of the substance of the gland, is probably at the bottom of many of these cases. The same train of symptoms supervenes not unfrequently upon organic renal disease. They happen too, sometimes, when the ureters become impervious, from disease, or from impacted gravel. In this condition urine continues to be secreted, for a time at least, and distends the ureter behind the seat of the obstruction. The apoplectic state which ensues may arise from a re-absorption of the secreted fluid; or, in consequence of the obstacle, the secretion itself, after going to a certain point, may stop, and then the case becomes a case of suppression.

Respecting the treatment of this most formidable condition I can say but little. Cupping upon the loins, venæsection if warranted by the state of the pulse, the hot bath, sudorific medicines, purgatives, and large warm enemata, seem to me the kind of remedies indicated. To endeavour to force the secretion of urine by strong stimulating diuretics, should strike one, *à priori*, as being hazardous. Yet this practice has its advocates; and, should experience declare in its favour, theoretic objections ought to be disregarded. If benefit is so to be obtained, probably the best drug for our purpose would be cantharides. Dr. Elliotson refers to some examples of its success in the hands of Sir Astley Cooper; and afterwards of another practitioner who took the hint from Sir Astley. He suggests that as the tincture of cantharides is a very uncertain preparation, the remedy should be given in the solid form, a grain at a time, and that a large blister should be laid upon the loins. Beyond these hints I am unable to give you any assistance towards the management of this obscure but serious complaint.

The opposite condition of the kidney, in respect to its peculiar function — that, I mean, in which its secretion is largely and morbidly *augmented* — is mostly as fatal as the total suppression that we have just been considering; but it is not so rapidly

fatal. When the amount of urine secreted and passed is permanently too great, when it is constantly running off, as it were, from the system, the patient is commonly said to have *diabetes*: from διαβαίνω, to pass through.

But it is not every case of an excessive flow of urine that deserves to be called diabetes. Great quantities of aqueous urine are passed by hysterical and nervous patients. We all make more water in cold weather than in warm; the functions of the skin and of the kidney compensating each the occasional defect of the other. Certain drugs and articles of diet are also well known to cause a temporary excess in the amount of urine secreted.

In fact, although the quantity of urine voided is the most obvious and striking symptom of diabetes, its definite and characteristic symptom is a most remarkable change in the *quality* of that liquid: in its becoming loaded with sugar. You will find, indeed, two species of diabetes mentioned by many authors—the diabetes *insipidus*, and the diabetes *mellitus*. The former term ought in my opinion to be abolished. If it refer merely to an unnatural abundance of urine, not otherwise differing in its composition from healthy urine than in containing a large proportion of water—by calling such a state diabetes we link together in the same genus two essentially different conditions. In true diabetes the urine is never without sugar. The quantity may indeed be small; and it may not be sensible to that coarse test, the *taste*; but modern observers almost all agree in rejecting any species of diabetes in which the urine is not at all saccharine. This condition of the urine was first described in 1684, by our learned countryman, Dr. Willis.

The sensible qualities of diabetic urine differ strikingly, in many particulars, from those of the urine in health. Its chemical quality differs strikingly too, as I have already told you; but it is in one particular only. Fortunately no extraordinary skill is required to recognize the morbid secretion.

Diabetic urine is commonly light coloured, and transparent; of a pale straw, or greenish tint. Being so copious, it rarely exhibits any visible lithates. Its odour is peculiar. According to Dr. Prout the scent somewhat resembles that of sweet hay, or that of milk: but to my nose it is more like the faint smell of certain apples, or rather of an apple chamber. Its taste is, more or less, decidedly sweet. Notwithstanding its limpid and aqueous appearance, diabetic urine is remarkably heavy. When boiled in a test tube with an equal quantity of liquor potassæ it assumes a claret colour of a greater or less depth, according to the quantity of sugar present. This is called *Moore's test*. Its delicacy may be increased, Dr. Garrod says, by *first* adding a drop or two of liquor potassæ to the urine, so as to make it slightly alkaline, and then decolorizing it by the further addition of animal charcoal, and by filtration through paper.

Another good and familiar test is that of *Trommer*. In a large test tube mix with some of the suspected urine just enough of a solution of sulphate of copper to give it a faint blue tint. Then add liquor potassæ in considerable excess. If sugar be present, a precipitate of hydrated oxide of copper first falls, which is redissolved in the excess of alkali, forming a dark blue solution. If this be gently heated to ebullition, a dense deposit of red sub-oxide of copper takes place.

Yeast, again, furnishes a ready and an easy test of saccharine urine. Invert a test tube filled with urine to which a small quantity of yeast has been added, into a saucer also containing urine. In a warm room, fermentation, if sugar be present, will soon commence, and carbonic acid rising in the tube will depress the upper surface of the urine.

What are called *torulæ*, minute vegetable confervoid growths, very soon appear in diabetic urine when it is freely exposed to the air in a warm place. This sugar fungus, as it is also named, has in fact been ascertained to be identical with the yeast plant; and during its growth (and probably in consequence of its growth) the urine undergoes the alcoholic fermentation, bubbles of carbonic acid gas are evolved, and a vinous odour arises. The presence of torulæ in the urine has therefore been regarded as good evidence of the presence of sugar also. But this is not a safe inference. Other confervoid forms, requiring an instructed eye to distinguish them from the sugar fungus, do often accompany it: and these are constantly developed in non-saccharine urine also, provided that it be acid, and that it contain albumen, or some other animal matter.

These other confervoid forms constitute stages in the growth of the fungus called *penicilium glaucum*, which is the same that so often gives to decaying animal or vegetable substances a mildewed or mouldy appearance. It has been recently asserted that the yeast plant, the *torula cerevisiæ*, is really identical with this *penicilium glaucum*. Dr. Arthur Hassall, however, in a very interesting paper on the subject, contained in the *Medico-Chirurgical Transactions*, affirms that these two fungi are readily distinguishable, the one from the other, under the microscope, and he gives drawings of both, in the various stages of their development up to their perfect fructification.

However this may be, if you observe torulæ in the urine of a patient, do not, unless you are expert microscopists, conclude at once that he is labouring under diabetes; but taking the hint which they furnish, employ other tests to determine whether his urine be really saccharine or not.

It was long believed that the quantity of urea in diabetic urine was reduced much below the natural standard; and that the sugar was somehow formed at the expense of the urea. Dr. Prout, in his earlier researches, always detected a little, and but a little, of this peculiar principle. Later observations have shown, however, that the urea is not so scanty; nay, that it is generally as abundant as in the urine of health, and sometimes even more so. The presence of the sugar conceals the urea; interferes with the action of the ordinary tests of that substance. By certain modes of procedure, which I need not stop to describe, the urea may readily be discovered: and it is often found, I say, to be rather excessive than deficient. The usual saline matters belonging to healthy urine are present also in that of diabetic persons; and in the same *relative* proportions; but, as might be expected, their *absolute* amount, in a given quantity of the liquid, is very much diminished. In short, the only essential deviation from the standard chemical constitution of the urine is, that it holds in solution a quantity of sugar. This explains its peculiar odour, its sweetness, and perhaps its excessive quantity. It accounts also for another very characteristic property of diabetic urine; I mean its high specific gravity. In general, you know, the specific gravity of the urine is inversely proportional to the quantity secreted in a given time; the more copious and dilute it is, the lighter it is. But in diabetes, so strong is the saccharine impregnation that the specific gravity more than keeps pace with the increased quantity of the liquid secreted. The specific gravity of diabetic urine is always much higher than that of healthy urine.

The *quantity* of urine secreted and voided is sometimes enormous; greatly more than could be supplied by the quantity of fluid taken as drink, although that, as I shall presently explain, is excessive too. A healthy person passes from one to three or four pints of urine in the twenty-four hours. The quantity, as you well know, is liable to considerable variation: perhaps the average may be safely laid at about forty ounces. But patients in diabetes will void 40 *pints* in the same time. I have myself known 26; 13 or 14 are not uncommon; and cases are recorded by writers of credit and veracity, in which 70 pints were passed daily. Nay, one Italian author declares that 200 pints have been discharged in that time.

The saccharine matter thus held in solution may be obtained in its solid form by evaporating the urine. I have seen large flat cakes of beautifully crystallized diabetic sugar. It differs somewhat from common sugar, the produce of the sugar-cane; and approaches more nearly to the sugar of grapes. This kind of sugar, which may also be produced artificially from starch, chemists have named *glucose*. By rapid evaporation of the water a thick syrup is procured, resembling treacle; but Dr. MacIntyre, who has presented to our hospital-museum some very perfect specimens of this sugar, prepared by Mr. Blandford, informs me that to get it well crystallized, the evaporation in a steam bath should be stopped while the urine is still of thin consistence. It may be quickly reduced to one-half, perhaps, of its original quantity. Then it should be set aside, in shallow plates; and in the course of ten days or a fortnight the sugar will be deposited in an irregularly crystalline mass.

The sugar is sometimes so abundant, that it undergoes a rude crystallization as the urine dries, wherever it happens to fall. A girl who was in St. Bartholomew's Hospital while I was a student there, observed that if her water were accidentally sprinkled upon her black stuff shoes, every drop left a white powdery spot behind it. So also an aged patient under Dr. MacIntyre's care expressed to him her alarm at finding that her black worsted stockings were sticky and covered with a white dust,

from the same cause. A man recently under my charge in the Hospital, complained that two pairs of his black cloth trousers had been spoiled in a similar manner. I remember hearing from a diabetic patient in the Edinburgh Infirmary, that his attention was first drawn to his urine by the number of flies and wasps which its sweetness attracted to the chamber-pot. In India the red ants have been observed to swarm in the same way about a vessel containing diabetic urine.

This daily production of sugar from the laboratory of the human body, is surely a very singular and surprising phenomenon. Sugar is not a constituent of healthy urine. Dr. Prout (whose experience on this subject was very large) says in his book that he had never known saccharine matter to occur in the urine of any other animal than man. I once had a coach-horse which I supposed might have diabetes. He was a greedy feeder, and drank eagerly, yet he grew thinner and thinner; and at whatever door I had occasion to stop, there he invariably began to stale: so that I became thoroughly ashamed of his leaking. Dr. Prout was good enough to examine his urine for me. It contained no sugar, but its healthy properties were much changed: it had less than the natural quantity of hippuric acid, and more of earthy matters. The disease, he told me, is known at the Veterinary College; whence specimens of such urine had been sent to him for inspection: but it is not true diabetes.

The unnaturally high specific gravity of diabetic urine is a constant quality; and you must attend to this, for it is almost always a faithful index, not only of the presence, but of the severity of the disorder. Dr. Prout places the specific gravity of healthy urine between 1015 and 1025, that of distilled water being represented by 1000. Different authors vary somewhat in their estimate of the natural standard; but we may be content to follow Dr. Prout. He says that the specific gravity of diabetic urine has been stated to vary from 1020 to 1050: that he has many times seen it higher than this, but very seldom so low. In fact it ranges generally between 1030 and 1060; and the average may be taken at 1040.

So much with reference to the quantity and qualities of the urine discharged in this complaint. It is attended, however, in well marked cases, with other and important symptoms, as you may suppose.

So much fluid being evacuated from the body through this channel, it might be expected that the *other* channels for the excretion of liquid matters would be comparatively dry: and so they are. The skin is arid, harsh, and unperspirable. The patients tell you that they never sweat: that they cannot get into a perspiration. This is a very general symptom; yet in some few patients, especially as the fatal period of the complaint draws near, the surface readily becomes humid. And a friend and patient of mine, whose urine was very copious, and contained a notable amount of sugar for several years together, without any perceptible abatement, however, of his general good health, perspired profusely every night. Again, the bowels are mostly costive, and the *faeces* remarkably solid and free from moisture. The tongue is dry, parched and sticky; sometimes unnaturally red and clean: and the waste of watery particles from the system seems to be felt and expressed by the inordinate thirst which the patients suffer. Their drought is often insatiable. I remember one girl's telling me that when she was debarred from an excess of water to drink, she would get up if she heard it raining in the night, and catch some of the descending drops to satisfy the tormenting sensation of thirst. And another patient, a very sensible fellow, informed me that, believing that it could not be good for him to drink so much, and feeling no confidence in his own resolution to refrain, he was in the habit of betaking himself in the summer time to the fields and dry pastures, where no water was at hand to quench his strong desire for it. The appetite for food is often, but not always, equally keen: and the patients, especially those in the lower ranks of society, are apt to think, while wondering at their loss of strength, that there cannot be much the matter with them, since they continue to eat and drink so famously.

Again, the enormous daily drain upon the system may be expected to cause various symptoms and sensations, which may all be referred to weakness and defective nutrition. A table has been published by Dr. Henry, showing the quantity of solid extract in every wine pint of urine of different specific gravities from 1020 to 1050. Taking 1040 as the average specific gravity, and ten pints as the average quantity, of the urine discharged daily, the patient would in this manner lose, every twenty-four

hours, 15 ounces 7 drachms—or more than a pound and a quarter—of solid materials. Dr. Garrod, after analyzing the urine in several cases of diabetes, found the daily quantity of sugar excreted to vary from half a pound to a pound and three-quarters. It is most abundant three or four hours after a full meal, and least abundant when the secretion takes place at the time most remote from the influence of food.

We need not be surprised, then, at the hunger, the wasting, the hectic fever, the feeling of emptiness and sinking at the stomach, the debility, the chilly state of the body, and especially of the extremities, the aching and sense of weariness in the loins and legs, the aversion to exercise, the loss of virility; all of which symptoms are generally present. I may add, to complete the picture, some others, enumerated by Dr. Watt, and confirmed by Dr. Prout, and consistent with my own experience of the disease. They are, uneasiness in the stomach after meals, flatulence and acid eructations, dimness of vision, redness of the whole interior of the mouth, sponginess of the gums, looseness of the teeth, and some degree of irritation and inflammatory redness about the external orifice of the urethra: these last are symptoms noticed in persons dying of inanition. Again, listlessness and depression of spirits, weakness, and peevishness of temper: “the once vigorous mind becomes feeble, oblivious, and vacillating—the once amiable temper, fretful, suspicious, and intolerant.” With all this there is a peculiar faint and unpleasant odour of the breath and person; an odour which Dr. Prout says is hay-like, which some call melleous, but which reminds me, as I said before respecting the urine, of the smell of a room in which apples have been kept. I have often recognized the complaint, upon first entering the sick chamber, by this peculiar scent.

Diabetes is generally a chronic disorder, ereeping on at first insidiously, and spreading itself, under judicious management, over many years. Yet it is sometimes fairly entitled to be called an acute disease; for it occasionally breaks out suddenly, is attended with much febrile disturbance, and runs a short course, uncontrolled by any treatment. One such instance I have seen, and others I know of. Much more frequently it proves fatal through the supervention of some organic mischief, such as debility is calculated to foster and develop. It often becomes associated, in its progress, with pulmonary disease, especially with tubercular phthisis. So common is this, that some persons have thought it universal. But it is not so. I have myself witnessed more than one or two dissections of persons dead of diabetes, whose lungs did not contain a single tubercle. Sometimes the disease terminates in incurable dropsy: and sometimes the patient is cut off suddenly, either by apoplexy, or by some peculiar disorder of the stomach.

There is some kind of connexion between diabetes and certain affections of the skin, and of the subjacent reticular membrane. Dr. Prout remarks that it usually *follows* cutaneous complaints, but *accompanies* or *precedes* those which involve the areolar tissue. Persons have been known to lose chronic eruptions, upon the supervention of diabetes. On the other hand, carbuncles and malignant boils are frequently the companions of that disorder. Cut carbuncles and boils are not necessarily accompanied (as Dr. Prout suspected they were) with saccharine urine. Itching of the skin is not uncommon.

Dr. Garrod has found *gangrene* to be of frequent occurrence in diabetic persons. There can be no doubt that their vital power is always greatly lowered by the disease. They are apt to sink rapidly under any sudden mental shock, under bodily injuries, under surgical operations, and even under unusual fatigue or anxiety.

The same author remarks that upon the supervention of these secondary diseases the sugar frequently disappears from the urine; and cautions us that this disappearance, far from being an index of improvement in the patient's condition, is then really a warning of danger, and too often the harbinger of approaching dissolution.

The examination of the dead body throws little or no illustration upon the pathology of diabetes. We naturally look with interest to the kidneys. But we find nothing there to explain the symptoms noticed during life. What I have usually remarked has been a deep purplish red colour of the kidneys, which were veined and vascular, but not otherwise altered in texture. Andral and others tell us that the kidneys are found hypertrophied in diabetes. But hypertrophy, and unnatural vascularity, are circumstances which we are not surprised at, when we reflect upon the vastly increased quantity of work which the glands have been performing. We must

regard both of these unnatural conditions rather as being consequences, than as being causes, of the profuse and long continued flow of unnatural urine. In one instance, after sudden symptoms of gastritis, which followed the incautious potation of strong ale, I found the mucous membrane of the stomach distinctly inflamed, in its cardiac portion. I have seen also the mesenteric glands diseased, converted almost entirely into bone. But neither of these changes are constant. They were purely accidental in those particular cases.

What, then, is the origin and source of this strange complaint? whereabouts in the body is the sugar formed? is it made, by the kidneys, from the blood? That was one of the earliest conjectures. It was naturally thought that, if the sugar pre-existed in the blood, and was only withdrawn from it by the kidneys, it would be discoverable in the blood. Yet able chemists sought for it there in vain. Hence it was inferred, that by some new combination of its elements, saccharine matter was actually formed in the kidneys. The chemistry and the reasoning were both faulty. Sugar has, now, been detected both in venous and in arterial diabetic blood. It is detected with some difficulty, partly perhaps because its presence is masked by the albumen of the serum, but partly because its quantity is small; and its quantity is small because it is continually decanted out of the blood, as fast as it enters, and with it a profusion of water also, through the kidneys. In this respect the sugar and the urea are alike. They are both excretions which the blood is in haste to cast forth. It would seem also as if the sugar necessarily carried with it a large quantity of aqueous fluid from the blood, and was simply diuretic. When the amount of sugar eliminated is diminished, as by certain remedies it may be, the quantity of urine diminishes too.

Traces of sugar had, I believe, been found in the blood by some previous inquirers; but it is to Mr. M'Gregor, of Glasgow, that we are indebted for the full exposition of this interesting fact. His researches on this subject were published in the year 1837, in the *Medical Gazette*.

By a peculiar process, he did, I say, that which many preceding chemists had failed to accomplish; he detected sugar in the serum of the blood of diabetic patients. The serum had a milky appearance, he says; and I have seen that myself; its specific gravity was above the healthy standard. Having coagulated the serum by heat, he carefully dried it; then he cut the dried mass into very small pieces, and boiled them in distilled water; and lastly, he evaporated the decoction to a certain point. To the liquid thus concentrated he added a portion of yeast, and the presence of sugar was manifested by the fermentation which ensued, and which lasted for several hours. Yeast, I should have told you, is a very delicate test of sugar, and will readily detect half a grain in two ounces of liquid.

Mr. M'Gregor went a step further back. He obtained, by means of an emetic, the digested food from the stomachs of two men who had dined two or three hours before. One man was in health; the other had diabetes. In each case the food had been of the ordinary kind. Applying, after due preparation, the test of yeast, he found that the vomited matters fermented strongly; especially those from the diabetic patient.

Then he varied the experiment. Thinking that the sugar, in these cases, might have been introduced in the vegetable portion of the food, he adopted precautions to exclude that possible source of fallacy. He administered to a healthy man, and to a diabetic man, a vomit and a purge, to clear out the alimentary canal. Next, he fed them upon roast beef and water, and nothing else, for three days. Then, three or four hours after a meal, the contents of their stomachs were procured by the operation of the sulphate of zinc, as an emetic; and treated as in the former case. What the healthy man vomited did not ferment at all. What came from the diabetic patient fermented "pretty briskly."

The inference from these facts seemed direct and inevitable that the fault lay in the *digestive* organs; that instead of perfect and nutritive chyle, saccharine matter was formed by the stomach, and entered the circulation unaltered. In healthy digestion all amylaceous food is first converted, the chemists tell us, into glucose, which then undergoes further changes. In diabetes these further changes were somehow prevented. The food which should be transmuted into muscle, and fat, and bone, and nerve, and membrane, was hurried out of the system, as sugar, with the urine.

This plausible theory has been disturbed by the surprising discovery, made and au-

nounced by M. Claude Bernard, that within all healthy persons, whatever may be their food—nay, within all animals, whether herbivorous, carnivorous, or omnivorous—a manufacture of sugar is constantly going on. The apparatus for this manufacture is planted in the liver, in the tissue of which sugar may always be detected, while every other organ of the body is destitute of it. No sugar can be found in the blood of the portal vein: plenty of it exists in that of the hepatic veins, even when the food (as in experiments made upon dogs, and young owls) has been exclusively animal for months beforehand. The sugar is traceable onwards in that part of the vena cava inferior which lies between the entrance of the hepatic veins and the right auricle, in the right chambers of the heart, and in the pulmonary arteries. The rest of the blood, during the intervals between successive periods of digestion, is devoid of sugar. While digestion is in full process, the blood which has passed through the lungs contains a slight impregnation of saccharine matter, not enough, however, to reach, in any appreciable amount, the urine.

The sugar formed in the liver, disappears then, according to M. Bernard, in the lungs. The observations of Dr. Pavy, published in the *Guy's Hospital Reports*, make it probable that it is consumed in those organs, or converted into some other substance, perhaps into lactic acid.

Dr. Harley denies, however, that this sugar is wholly expended in the lungs; and states that it finally disappears in the capillaries of the general circulation.

Pushing his investigations somewhat further, M. Bernard has satisfied himself that, by a vital process, a substance analogous to vegetable starch is formed in, or by, the livers of all animals; and that, by a chemical process, this substance is convertible into dextrine, and sugar. Sugar continues to be produced in the livers of healthy animals, for some little time after their sudden death.

Pray notice, *en passant*, the remarkable fact brought to light in these researches, and wholly unknown and unsuspected before, that the liver exercises a twofold and contrasting office of secretion. While it separates outwardly and obviously what may be deemed an excrement from the blood, namely bile; it secretes, inwardly and occultly, an increment into the blood, namely sugar. This fact is pregnant with suggestions as to the probable functions of the ductless glands of the body, which have no outward secretions; the spleen, the supra-renal capsules, the thymus and the thyroid glands.

Another most singular discovery of Dr. Bernard's, connected also with the subject before us, is, that *artificial* diabetes may be produced at will in an animal by irritating (by means of a puncture, or of a slight galvanic shock) a portion of the floor of the fourth ventricle of the brain, close to the origin of the pneumogastric nerves. Within an hour or two the urine of the subject of the experiment becomes saccharine; and it continues saccharine for a whole day, or more; until (probably) the slight injury done to the nervous substance is repaired. He ascertained also that the sugar-forming function of the liver was suspended by division of the pneumogastric nerves. Not that the hepatic secretion of sugar is determined by the direct influence of those nerves; for pricking the floor of the fourth ventricle is followed by the appearance of sugar in the urine, even after the section of the pneumogastriacs, which must therefore be regarded, in respect to the sugar-forming power, as incident nerves.

From these interesting discoveries has naturally arisen a new and simple theory respecting the pathology of diabetes. Either the hepatic sugar is formed in excess; and there is more of it than can be consumed in the lungs, or in the capillaries of the general circulation: or, the natural quantity of sugar furnished by the liver fails, in some way, to be so destroyed. In either case the sugar, thus remaining in the blood, passes at length from that fluid into the urine.

But there are two facts which strike our attention at once as jarring somewhat with the simplicity of these conclusions. The natural secretion of sugar goes on in the liver of healthy persons irrespectively of the kind of food which they may eat: whereas the quality of the food has a most striking influence, as I shall presently show you, upon the amount of sugar in the blood and in the urine of diabetic persons.

And the doubt thus suggested concerning the sufficiency of the new theory is strengthened by some curious facts made known still more recently by Dr. Owen Rees. It has been found by himself, and by Dr. Pavy, that the hepatic sugar, and the sugar of artificial diabetes, which seem to be identical, and which may be distin-

guished by the name of *animal* sugar, differ sensibly from the sugar of true diabetes, which I have already told you is akin to the *vegetable* sugar derived from grapes. The reaction of the animal sugar with some of the tests is peculiar; but the main distinction is the facility with which it is destroyed when kept in contact with blood, or other animal matter. Grape sugar and the sugar of true diabetes possess a power of resisting decomposition far stronger than that which exists in the sugar obtained by producing artificial diabetes. "There is little doubt," says Dr. Rees, "that the sugar of diabetes is a higher quality of the saccharine principle, and that it can preserve its atomic arrangement with much greater force than the hepatic variety."

The great problem therefore is not yet solved, although we seem to have come nearer to its solution. Meanwhile a large field is left open for conjecture and query.

It is probable enough that the exciting cause of diabetes may sometimes lie in the digestive organs, as Mr. McGregor supposed. The results of his experiments do not conflict with M. Bernard's. Mr. McGregor, you may remember, found sugar in the partly-digested food brought up from the stomach of a diabetic patient. He detected it also in the saliva; and in the feces, which when allowed to dry spontaneously, became covered, after the lapse of some time, with distinct crystals of sugar. And yeast having been administered to two diabetic patients in ounce doses after each meal, had soon to be discontinued because the patients, to use their own expressions, felt as if they "were on the eve of being blown up." There being sugar in the blood, we need not be surprised that he met with it in the gastric and intestinal secretions from the blood. Dr. Harley has observed that by injecting irritating matters into the portal vein (ammonia, ether, chloroform, alcohol) a saccharine condition of the urine may be artificially produced. It is conjectured that these substances act upon fibres of the pneumogastric nerve, whence an impression is transmitted to the nervous centres, and thence is again reflected upon the liver through the splanchnic nerves. It is not difficult to imagine that irritating substances may find their way into the portal blood, through a faulty digestion, or through the use of certain kinds of food or of medicine. Again, since contrived irritation of the brain at the origin of the pneumogastric nerves will make the urine saccharine, the cause of diabetes in the human subject may reasonably be placed, in some instances, within the skull; and we may understand how injuries or diseases of the brain, or even mental disquiet and dejection operating through the brain, may produce it. Some striking cases have been published by Dr. Gooden, in which head symptoms were accompanied by saccharine urine, and in which the diabetic symptoms were checked or removed by remedies addressed to the head affection; by blisters especially, and by purgatives. Nay, we may ask whether there may not, in fact, be two varieties of diabetes mellitus, in one of which the animal, and in the other the vegetable, form of sugar may be present in the urine: and whether the one of these varieties may not be more hopeful of cure or recovery than the other. Bearing in mind the name and the distribution of the pneumogastric nerve, may we not indulge the conjecture that disease or injury of the brain near the origin of that nerve may directly affect the functions of the *stomach*, and thus prevent its digestive power—or the functions of the *lungs*, and thus interfere with the chemical destruction of sugar in those organs. This last notion might seem to receive support from the frequent association of pulmonary disease or disorder with saccharine urine.

Dr. Rees appears disposed to place the main error in the hepatic functions; and to suppose that in diabetes the liver, from some diseased action in itself, or in the organs that influence it, "produces sugar differing from that of health—a sugar which cannot be destroyed by the changes taking place naturally in the blood—changes rapidly affecting and destroying healthy hepatic sugar." After showing how readily the different varieties of sugar are convertible into each other by simple processes, Dr. Rees adds some observations so new and so suggestive, that I shall take leave to read them to you:—

"In reflecting on the phenomena of this important disease, we are naturally led to consider the anatomical relations of the organs most obviously concerned in its causation; and the stomach and liver must most especially present themselves to our notice. The position of these organs—situate as they are in the immediate vicinity of the central masses of the sympathetic, the semilunar ganglia and the splanchnic nerves, and supplied also with branches having immediate connection with the cerebro-spinal

system, — is in itself suggestive of the high importance of the offices discharged by them, of their sympathies and close relation. In this part, then, of the living and moving organism, a most intimate union is effected between the sympathetic and cerebro-spinal systems—systems presenting a curious and doubtless intentionally different arrangement as regards their chemical relations, and one which has been (as far as I can ascertain) entirely overlooked by physiologists; an arrangement having most certainly a deep meaning, and one which I fully believe is to throw light on many obscure problems in medical science. I allude to the distribution of the ultimate fibrillæ of the sympathetic and cerebro-spinal systems. Thus the ultimate extremities of the sympathetic are almost entirely spread over parts possessing an alkaline reaction, while precisely the opposite is the case with the fibrillæ of the cerebro-spinal system. The former lie in mucous and serous surfaces, and in the blood-vessels, bathed with alkaline fluid; the latter lie in muscular fibre, and in the cutis as cutaneous nerves, and in both cases are bathed in strongly acid secretions. Now there is no part of the organism to which we can point in which these chemical affinities are so freely interwoven as in the neighbourhood of the liver and stomach; and here again we are attracted by the peculiar nature of the secretions poured out by these organs. They seem to be exceptions to the general rule—to be the parts, as it were, acted upon by the electro-chemical arrangement, and parts to which it is subservient.”

We know but little about the outward causes of diabetes. It is not a very common disorder; and in those who become afflicted with it, there probably has existed a predisposition to it. Dr. Prout remarks that the complaint runs sometimes in families, and is inherited. I had under my own observation, for some time, three children, two brothers and their sister, all affected with diabetes. The mother, a maternal uncle, and a sister of a friend of mine, all died of this malady. The same author mentions among the predisposing causes, long-continued intemperance, and especially the immoderate use of spirits, severe evacuations, excessive labour joined with a poor acescent diet. Distress and anxiety of mind are held also, and justly I think, to be among the predisposing causes. It occasionally seems to be produced, at once, by the operation of some exciting cause, such as exposure of the body to cold; or the drinking of large draughts of cold fluid while the drinker was hot and perspiring. Dr. Bardsley states that, in twelve instances of the disease which had fallen under his own notice, the patients attributed their ailment to one or the other of these two causes. Now these are common causes of disease; and that a predisposition does exist is probable from the fact, that where the exciting cause has acted on several individuals at the same time, one alone has become affected with diabetes. There is a narrative illustrating this, by Sir Henry Marsh, in the third volume of the *Dublin Hospital Reports*. A patient of his traced the apparent origin of his diabetes to exposure to wet, cold, and privation, at sea, while in imminent danger of shipwreck. Another of the crew fell ill of ague. Others escaped entirely, or had only common colds.

Diabetes is a malady which justly alarms those who are the subjects of it. But though too often a fatal malady, it is not necessarily so: and the older I grow, the less despondence do I feel upon first ascertaining that a patient is voiding saccharine urine. Whether it be that the disease is really more common, and at the same time milder and more tractable than it formerly was—or whether (what seems more likely) it is more carefully looked for now-a-days, and more easily recognized, certain it is that I both see, and hear of in the practice of others, many more instances of diabetes than I did some years ago. Of the well-marked cases, a few—not many—have recovered perfectly, and so far as I know permanently, even to the return of the urine to its natural specific gravity. Others have gone on, by slow or by rapid steps, to a fatal termination. In not a few, the main symptom of the complaint, I mean a considerable impregnation of the urine with sugar, has continued for months and years, without material deterioration of the general health, until the patient has been cut off by some other illness. It would seem that when the digestive organs are capable of properly assimilating a sufficient quantity of food to sustain the bodily fabric, other portions of the aliment may run off in the form of sugar with comparative impunity to the health. But even this, the best state in which a person who remains diabetic can be, is a perilous state.

I must caution you against a premature conclusion that your patient is well. Apparent recoveries—nay, apparent cures—are not very uncommon. And this it is of great importance to know. Remedies are not useless because they fall short of their full scope. It is better to keep a man on the edge of a precipice, if you cannot pluck him away from it, than to let him fall over. And many diabetic patients are kept in this predicament of dangerous safety. There are certain remedies that exercise a strong controlling influence over some of the most prominent and troublesome of the symptoms; and that sometimes even restore the patient to a state which he mistakes for health; and which a medical man, unwarned of its fallacious character, might also mistake. The urine may recede within its natural limits. There may remain *one* morbid circumstance only, and that of a nature easily overlooked: indeed it is sure to escape observation if it be not especially searched after. I allude to the unnaturally high *specific gravity* of the urine. So long as the density of the urine continues permanently and decidedly above the healthy standard, there is no real security. The smallest disturbing cause—exposure to cold, an intemperate meal, unusual exertion and fatigue, sudden or strong mental emotion—may bring back all the symptoms in their former severity. If these and similar hurtful agencies can be averted, life may sometimes be prolonged, in much comfort, for many years.

In an interesting paper, which you may see in the 36th volume of the *Medico-Chirurgical Transactions*, Dr. Bence Jones calls attention to cases of *intermitting* diabetes, of which he relates several. The peculiarity of such cases is, that without obvious cause the sugar disappears from the urine at intervals; and sometimes just before these intervals occur, the urine is found to be full of free uric acid, and of crystals of oxalate of lime. He notices also, and partly confirms the observation of Deschambre, that sugar is frequently present in the urine of old people without producing very urgent symptoms: sometimes, indeed, with none of those symptoms which would naturally suggest a search for it.

In the treatment of every case of diabetes, there are three objects to be kept in view.

First, to restore the defective power of the digestive apparatus, whether the fault be in the stomach or in the liver:

Secondly, to cut off, or restrict as much as possible, the supply of saccharine matter from without:

Thirdly, to mitigate or remove the most distressing symptoms.

If we could achieve the first of these objects, the other two would fall out of sight; for the disease, which may be regarded as a variety of dyspepsia, would be cured. But hitherto the resources of our art have, in this respect, been baffled. Our main hope of ultimate success must lie in the regulation of the *ingesta*; whereby, also, the second indication is to be fulfilled. *Some* of the food is, in every case, carried to the proper account, or the patient would speedily die. If we can succeed in directing a sufficient amount of healthy nutriment to the organic tissues of the body, the draining away of any superfluous sugar will be borne well enough.

About the beginning of the present century, Dr. Rollo discovered and taught that a diet composed exclusively of animal matters had a signal effect in reducing the quantity and in diminishing the sweetness of diabetic urine. And the reason of this is obvious. Animal food furnishes but scantily the materials for the formation of sugar. "The saccharine alimentary principles are chiefly derived (says Dr. Prout) from the vegetable kingdom, and indeed constitute what may be called, by way of distinction, *vegetable aliments*." If then, we exclude aliments of this kind, and confine the patient to animal food alone, we thus cut off at least one supply of the *materies morbi*; and without indeed curing the disorder, suspend its worst effects. But unluckily very few persons can long endure this mode of living. So far as they can endure it, they are comparatively safe. We are obliged to relax a little, sometimes, the rigour of our rule; and it is curious to observe how suddenly and decidedly the saccharine properties and the quantity of the urine are augmented, when, by stealth, or by permission, the patient adds to his meal the smallest portion of vegetable food—even a biscuit or two.

I quite agree with Dr. Garrod in believing that the regulation of the diet constitutes by far the most important part of the treatment. If care be taken to exclude all articles of food that contain saccharine matter, or that are readily convertible into saccharine matter, the condition of the patient improves at once. His thirst abates,

his appetite becomes more natural, the state of his tongue and of his skin improves, and his strength and weight augment. In one example, recorded by Dr. Garrod, the daily amount of urine was reduced within a few days, by regimen alone, from 354 to 100 fluid ounces, and the daily quantity of sugar voided with it from 26 ounces avoirdupois to rather less than 4.

In another instance, the quantity of urine under the ordinary diet of the hospital, averaged 267 fluid ounces daily. The patient being then put upon meat diet, the bran-loaf, cod's liver oil, and laudanum, the urine sank in quantity, in five days, to 91½ fluid ounces. And it rose again to 216 ounces upon the resumption by the patient of the ordinary diet.

In both these cases the general symptoms underwent a proportional improvement, as the amount of urine became less.

We must contrive then to vary the animal diet as much as we can; encouraging the patient by a free license to choose among the different kinds of meat, game, poultry, fish, and eggs, in their diversified modes of preparation, and admitting into his bill of fare as small an admixture as possible of vegetable substances. Green garden-stuff, the oleracea, spinach, cabbage, celery, water-cress, lettuce, and the like, may be taken with less risk of increasing the saccharine matters in the system, than potatoes, and those other articles of vegetable diet which contain a notable proportion of sugar or of starch. All kinds of fruit must be forbidden. You will seldom be able to debar your patients entirely from bread: none should be allowed but such as is well fermented, and somewhat stale, or thoroughly toasted; and even that as sparingly as may be.

The *bran-loaf* just mentioned — or, which are better, *bran-cakes* — form an excellent and not unpalatable substitute for ordinary bread. But they require to be carefully made. You may find Mr. Camplin's directions for making them, in the 38th volume of the *Medico-Chirurgical Transactions*, in a paper by that gentleman upon the *juvantia* and *lædientia* in diabetes, suggested by experience of the disorder in his own person.

It is of some importance to admonish the patient, whose appetite is generally ravenous, against eating too large a quantity, even of animal food, at any one time. Not only is the digestion still further weakened and oppressed by an intemperate meal, but the patient's life may be put in peril by every such act of unwise indulgence. Of this I have witnessed one example, and have heard of several more.

The quantity of drink should likewise be limited. It may properly enough consist of animal broths: and these should be taken *tepid*, for they are then more likely to be taken in moderation. The patients must, however, and will, have something else, to slake their urgent thirst. I have found (acting upon a suggestion of the elder Dr. Latham's) that distilled water, acidulated with phosphoric acid, appeases, more than most things, that painful sensation. The water of the Bristol Hotwell, which contains carbonate of lime in solution, is praised by Dr. Prout for the same purpose. Claret, as it contains no sugar, is an excellent and agreeable beverage for diabetic persons who can afford to drink it.

Dr. Christison gives an important caution in respect to drinks; viz., that, when the thirst has already been much indulged, the quantity of liquid taken must not be greatly reduced all at once. Sudden failure of the vital powers has not unfrequently ensued upon abrupt changes of that kind.

Very numerous are the remedies which have been tried, and which have been recommended for this disorder. I shall notice those only of which I have had personal and in some degree favourable experience.

The first of these is *blood-letting*, which has been strongly advocated by Dr. Watt, of Glasgow, and by Dr. Satterley, formerly one of the physicians to the Middlesex Hospital. It is not a remedy which would naturally occur to one's mind as being likely to prove of service in such cases; but both the authors I have mentioned speak of it in terms of high commendation. They affirm that, under small and frequent bleedings, the strength increases; the clamminess of the mouth, and dryness of the skin, diminish; and the blood, by degrees, assumes the buffy coat. I have once seen the method of frequent blood-letting put fairly to the test. At first the patient did seem to be benefited by it; but she ultimately died: and I am satisfied that her death

was accelerated by one bleeding too many, or by too large an abstraction of blood at one time.

This measure has the best chance of being useful, when the malady is recent, and attended with febrile disturbance. In chronic cases, in old persons, and whenever the debility is already great, venæsection can seldom be requisite or proper; although even then, as Dr. Prout remarks, it may be borne better than one might expect. Local bleeding is, however, of much service in relieving local uneasiness. Leeches may be applied to the epigastrium, if the patient have tenderness there, or complain of a sense of fulness or of burning in the stomach. Cupping to the loins, if they greatly ache.

Opium is a treasure to us in this disorder. It quiets the nervous irritability of the patient, allays many of his most distressing sensations, and restrains in a remarkable manner the morbid profluvium from the kidneys. But you must not suppose, from observing these favourable changes, that you are curing the disease by it. It appears to control the diuretic influence of the sugar in the blood; but it does not banish the sugar itself. And, as far as my experience goes, Dr. Prout is in the right when he states that moderate doses of opium generally suffice to check the excessive discharge. From three to five grains of Dover's powder, for example, three times a day, will do as much good, and on the other hand be productive of far less inconvenience, than larger quantities of that narcotic substance. The sudorific properties of this compound are thought to render it eligible: although it has seldom any apparent effect, in that way, in diabetes. If the ipecacuan which it contains should disagree with the stomach, an equivalent quantity of any other preparation of opium may be substituted for it.

There is another remedial measure which has also, in some cases at least, a most beneficial influence on the condition of the patient; I mean forced perspiration—perspiration induced by the hot-air bath. Of this I have seen some striking examples. A very well-marked case of diabetes came under my care in the Middlesex Hospital several years ago. A vapour, or hot-air bath, had just then been constructed in the hospital, and I thought it a good opportunity for trying whether the suspended functions of the skin might not be restored, and the extravagant action of the kidneys perhaps corrected, by that powerful mode of exciting perspiration. I should tell you that other plans of treatment had already been put in force, with but partial advantage. It would occupy more time than I can now spare to enter upon the details of this case; but I will read to you the man's own statement which he wrote down before he left the hospital, in evidence of the benefit he derived from the *sudatorium*.

"The urine" (these are his words) "is reduced more than one-half, and does not contain much sweetness, but sometimes tastes salt, with a mixture of bitter. My stools, which were dry, and like balls packed together, are now quite natural. The pains in my limbs are entirely removed. My spirits, which were very much depressed, are now revived and cheerful. The unpleasant aching of my kidneys, of which I spoke little lest I should be cupped in the loins, is now removed, only I feel weak there. I am cured of the pain in my stomach, and the circuitous working of the wind in my bowels, which formed lumps in my belly as it passed, resembling those formed by the cramp. I have likewise got rid of the palpitation at my breast, which was accompanied with a sort of dread. My breathing is much improved; perspiration in a great measure, restored; and my skin, which was dry, is now become moist. I sleep well at night, whereas I *could* not sleep more than two or three hours out of the twenty-four. My thirst, which was excessive, has ceased to be troublesome."

This man, who, in the statement I have just read, has so graphically described his own morbid sensations, and the relief from them which he had obtained, left the hospital thinking himself well; *but*, the specific gravity of his urine remained above 1030.

In about half a year afterwards, he went one evening to Hyde Park to see some fireworks, got wet feet, and began to cough. The diabetic symptoms returned more severely than ever; and he soon died. I found his lungs stuffed with tubercles.

In furtherance of the principle upon which the use of the hot bath is recommended,

the other well-known methods of promoting the natural functions of the skin should be followed; friction, and more especially warm clothing.

Steel is sometimes singularly beneficial in repairing the strength, and enlivening the spirits; as indeed it is well known to be in other forms of disease attended with a copious and permanent drain upon the system, and with a diminution of red blood. Of course it may be combined with opium or with any other medicine which the circumstances of the patient may render needful.

I scarcely need say that the bowels require attention. Not that active purgation is advisable, but simply their regulation. Castor-oil, rhubarb, aloes, lenitive electuary, are more appropriate in these cases than the purgative salts, which are apt to be diuretic also.

There is one other drug from which I think I have seen beneficial effects. I mean the *creasote*. I first became acquainted with its virtue from prescribing it, almost accidentally, until a consultation could be arranged with Dr. Prout, for a child, eight years old, in whom the disease was well marked, and who had been brought to London from the country for advice. She had been rapidly wasting away for ten weeks, was extremely feeble, soon tired, very thirsty, especially at night, and had (what was also new to her) an enormous appetite. She was passing from three pints to two quarts daily of pale urine, having a specific gravity greater than 1040. I desired that her diet should be as exclusively animal as she could bear, and that she should take one minim of creasote, suspended by means of mucilage in an ounce and a half of water, three times a day. Curiously enough, the child liked the tarry flavour of the medicine. Upon this plan, with gentle aperients occasionally to regulate her bowels, she remained for upwards of a twelvemonth. Her urine soon fell in quantity within the limits of health, and in density to about 1030. She regained her lost flesh, strength, complexion, and spirits, and grew considerably. At length she suddenly sank under an obscure affection of the chest. A brother of this little girl has lately manifested unequivocal signs of the same complaint; and in him it appears to have been equally checked by the same method of treatment. I have detected sugar in the urine of another boy belonging to the same family.

There were two points in this young lady's case which deserve a passing remark. As her urine diminished in quantity it began to deposit the lithates. This Dr. Prout considered a very promising earnest of a return to a better diathesis: and I find that in cases which have crept on insidiously from the first, he was accustomed to *date* the malady from the time when lateritious sediments, previously common, disappeared from the water.

The other point was, that calomel always sickened this child, and aggravated all the diabetic symptoms. This is consistent with Dr. Prout's experience, who tells us that he has never seen mercury do good in diabetic disease; but on the contrary almost invariably do mischief. I would advise you to read his judicious observations upon the too common abuse of that mineral.

I am quite aware of a possible fallacy in the case I have been mentioning, with respect to the efficacy of the creasote. With the use of that drug was associated a strict adherence to a purely animal diet; and it is impossible to estimate with precision the separate effects of these two remedial measures. I have frequently prescribed the creasote with similar results. It would however, in my opinion, be a mistake to go on increasing the dose. To most stomachs it proves irritating and hurtful when pushed beyond a certain small amount. The late Dr. MacIntyre told me that he had found the creasote very useful in diabetes. I must however acknowledge that, in common with others, I have sometimes been totally disappointed by it.

For many years of my professional life I had not met with an instance of what has been termed diabetes *insipidus*: from which I infer the rarity of that disorder. I shall use the term *chronic diuresis* to express this affection.

Very recently a marked instance of such chronic diuresis has presented itself in the hospital. A boy, eleven years old, not unhealthy looking, but lean, was admitted there under my care. He was much troubled by thirst; and by frequent micturition, which even in the night disturbed him many times. His bowels were costive, he had a capricious appetite, and his skin was dry. He voided during the twenty-four hours several pints, seldom less than nine or ten, of simply dilute urine, of a faintly yellow-

ish hue, and having the specific gravity of 1002. Sometimes, indeed, it was found to be scarcely heavier than distilled water. In other respects he appeared tolerably well. It was supposed that he had been affected for about twelve months; his desire for drink having been the first symptom noticed.

During his residence, of many weeks, in the hospital, under my observation, I made trial of every plan and drug that I could think of, for repressing the unnatural flux of urine. Nothing did him any good: some things, I fear, by disturbing his stomach and bowels, did him some temporary harm. He went out much as he came in.

Some of these cases appear to depend upon excessive thirst, arising from an unhealthy state of the mucous membrane of the pharynx, and are apt to end in phthisis. M. Becquerel has applied to the disorder the title of *polydipsia*. I have mentioned the foregoing example because it afforded me a proof that liquid may be absorbed into the body from the atmosphere; either by the external skin, or by the pulmonary mucous membrane, or by both these surfaces. Dr. Prout, to whom I showed both the urine and the patient, advised that, for a time, his supply of drink should be limited. Accordingly, very much to the poor boy's sorrow, he was put upon a daily allowance of a pint and half. I have no doubt that my injunctions were strictly observed, both by himself and by the nurses. Nevertheless, without losing flesh or weight, he passed, during the corresponding twenty-four hours, ten pints and a half of urine.

I got evidence of the same fact in another way also; namely, by weighing the boy at short intervals: although the experiment was not repeated so often as I wish it had been. I give you the results of one of these trials.

Immediately after he had emptied his bladder, he was found to weigh 3st. 8lb. 0oz. 3dr. Three hours subsequently, having taken nothing in the interim, he weighed 3st. 9lb. 0oz. 2dr. Then he voided 16oz. of urine: after which his weight was again 3st. 8lb. 0oz. 3dr. So that he must have imbibed about a pound of liquid in that brief space of time.¹

In this instance there was merely an excess in the aqueous ingredient of the urine: the solid matters were apparently there, in their due proportion to each other, but in a very small ratio to the water.

But the aqueous ingredient may be in excess, while the absolute quantity of *urea* is deficient. On the other hand, with an excess of the watery material, there may be an excess also in the quantity of *urea* it contains.

Dr. Willis has distinguished these three varieties of chronic diuresis by the terms *hydruria*, *anazoturia*, and *azoturia* respectively. Although I am no friend to the multiplication of technical names, I must tell you that the distinctions expressed by these terms are real, and of some importance. Anazoturia we shall find to be often symptomatic of a peculiar organic disease of the kidney, which I hope to describe in the next lecture.

Azoturia, which is accompanied by an unnaturally high specific gravity of the urine, is apt, on that account chiefly, to be mistaken for diabetes. As recoveries from it are not uncommon, it may be suspected that some of the boasted cures of diabetes were cures of this less serious disorder. In the one case, the yeast-test detects the presence of sugar in the superabundant urine; in the other case it finds none.

¹ This boy lived more than two years afterwards, and continued to void an excessive quantity of pale, neutral urine, scarcely heavier than distilled water. After death, scrofulous tubercles were found in his brain, and in his lungs. His kidneys were gorged with venous blood, but of healthy structure. There was nothing wrong, apparently, in his organs of digestion.

LECTURE LXXVIII.

Albuminous Urine. Means of detecting the Albumen. What it imports. Anatomical characters of Bright's Kidney. Symptoms to which this renal disease gives rise. Nature of the affection.

ANOTHER morbid condition of the urine, imperatively demanding your attention, is that in which it is habitually impregnated with *albumen*. This albuminous condition is much more common, and in general not less serious, than the saccharine condition which I described yesterday.

There is no albumen in healthy urine. Neither can we recognize its presence, in any urine, by mere inspection. We detect it by certain tests: and I will tell you, in the first place, what these are; and how to use them.

Albumen—of which we have so familiar an example in the “white” of eggs—begins to pass from the fluid to the solid state at the temperature of 160° *Fahrenheit*. When diluted it may require for its complete coagulation the heat of 212° . Hence one simple and easy test of its presence. We discover that albumen is contained in the urine, by heating that fluid to the boiling point. This is most conveniently done in a small glass tube, by the flame of a spirit lamp. It is seldom that any preparation of the suspected urine is requisite. It may, perhaps, be hazy in consequence of its containing *mucus*; and if its transparency be much troubled, it will be well to filter the fluid before testing it. When, as sometimes happens, albuminous urine is already turbid from the presence of the lithates, these dissolve as the heat is applied, and the urine first becomes clear; and then, as the temperature rises, the albuminous opacity begins to be visible.

The phenomena observable in the heated urine vary in different cases, chiefly by reason of the variable amount of albumen. The whole is sometimes converted into one gelatinous mass: but this is uncommon. Usually the albumen first appears in the form of a whitish cloud, of which the constituent particles multiply, and collect, in proportion as the quantity is considerable, into small curdy fragments or flakes. These soon subside to the lower part of the tube, leaving the supernatant liquor clear. The amount of albumen is of course to be estimated by the height to which, after such subsidence, the tube is filled by it.

Now this test, by heat, is not conclusive, nor sufficient. There are circumstances that may impede or prevent its effect in coagulating albumen, which, nevertheless, is present. On the other hand it may, under other circumstances, produce a fallacious appearance of albumen where none exists.

Albuminous urine has often a less acid reaction with litmus paper than healthy urine. The reason of this I will explain presently. When recently discharged from the bladder the urine may be neutral or even alkaline; or it may become neutral or alkaline, by spontaneous decomposition after it has left the bladder. In any case, the urine thus alkaline or neutral will not coagulate when heated, even though it may be full of albumen. The alkalescence must be owing to the presence of ammonia, or of soda; but the compounds formed by albumen with these alkalies are neither of them coagulable by heat.

Again, although there may be no albumen, heat may cause a flaky precipitate, consisting of the earthy phosphates.

We avoid, or we remedy, these sources of fallacy, by testing the suspected urine with nitric acid also, which has the property of precipitating the albumen in a flaky or pulpy form. It will thus detect albumen when the tested urine is alkaline. It has likewise the effect of redissolving the spurious precipitates which may be thrown down by the application of heat, and consequently of showing that they are spurious.

Nitric acid alone, however, is not, any more than heat alone, an unequivocal touchstone of the presence or absence of albumen: for if the lithates, or even if urica, be present in excess, a buff-coloured amorphous precipitate of lithic acid may be thrown down—or nitrate of urea may be formed—upon the addition of nitric acid, when there

is no albumen. But this defect is compensated by the complementary criterion of heat; these precipitates being redissolved by raising the temperature of the urine, while any coagulated albumen remains insoluble.

And always this test, by nitric acid, requires to be applied with a certain degree of care and delicacy. The risk is, of being misled through using too little of the acid, or too much. The compound resulting from the union of nitric acid with albumen—what may be roughly spoken of as the nitrate of albumen—is soluble in water, and is not coagulable by heat. If, therefore, just so much nitric acid (and no more) be mixed with the urine, as combines with all the albumen that it contains, no precipitate will take place. But when more is added, the nitrate of albumen, being insoluble in dilute nitric acid, becomes at once apparent in the fluid. Again, any great excess of nitric acid may redissolve the albumen.

Hence, in testing suspected urine, it is better to operate on a small quantity of it, a fluid drachm for instance, filtering it first if it be cloudy, then boiling it, and then dropping into it two drops of nitric acid: instead of nearly filling the test tube with urine, and adding a drop or two only of the acid, as is often done—or of adding as much acid as there is urine, which is perhaps a less common mistake.

Also, take care that your test tubes are *clean*; and do not contain, as they may do if merely just emptied, any trace of acid, or of alkali.

Furthermore, albuminous urine of excessive acidity, from its containing a free acid, may fail to exhibit albumen when heated. Either the acetic, or the hydrochloric acid will prevent it: in other words, the acetate and the hydrochlorate of albumen are both of them soluble in water, and uncoagulable by heat.

This source of error is also to be obviated by the addition of a small excess of nitric acid, after heating the urine: so that by observing the directions just given, you may avoid all risk of mistake.

Other chemical tests there are, frequently spoken of, and sometimes recommended: particularly the ferrocyanate of potass, corrosive sublimate, oxalic acid, and creasote. They are unnecessary, in addition to heat and nitric acid; and they are liable to fallacies from which these last, when combined, are free. Unless you are expert chemists, you had better avoid them.

Dr. Bence Jones has suggested the following simple and ready trial, when chemical materials happen not to be at hand. Evaporate a drop of the suspected urine on a slip of glass over a water bath. When the evaporation of the water is completed, any albumen which may be present will adhere to the glass so firmly, that it will be no easy matter to clean it. The evaporation may be effected in a few seconds, in a watch glass, over a spirit lamp, care being taken to hinder the urine from boiling, by holding it far from the flame.

Now it is quite certain that the presence of albumen in the urine does often accompany and bespeak a very serious organic disease of the kidney. For this disease we have no appropriate name. I wish we had. Some call it *granular degeneration* of the kidney, but the epithet granular is not always applicable. It is most familiarly known, both here and abroad, as *Bright's kidney*, or *Bright's disease*; after the eminent physician who, in 1837, first described it, and showed its great pathological importance. These are odd-sounding and awkward terms; but in the lack of better I must employ them.

It is very difficult to describe, in words, the anatomical characters proper to this renal disease; for they are neither very definite nor very constant. I am speaking now of that coarse anatomy of the diseased organ, which is cognizable by the unassisted vision. The rough sketch that I am about to attempt will be made more intelligible by Dr. Bright's plates, and those of M. Rayer, which are both before you.

The morbid appearances presented by the substance of the kidney are such as denote some change in its intimate structure. Its cortical (or secreting) portion is the primary and chief seat of this degeneration; yet what is called its medullary (*i. e.*, its excreting) part, is also sometimes implicated, but in a less degree.

These morbid appearances relate to the size, figure, and consistence of the kidney; to the colour and condition of its surface, and of its interior. With respect to some of these points there is much variety in different cases; and studying this variety under the light which is thrown upon it by the clinical history of the disease, we have reason to believe that, in part, it is connected with different stages of the disorgani-

zing process. Partly also, and perhaps chiefly, it appears to be the result of essential differences in the nature of the intimate structural changes. Thus if we look to the *size* of the diseased organs, they are sometimes much larger than natural, sometimes of the ordinary magnitude, sometimes considerably smaller. The average weight of the adult human kidney is between four and five ounces. In this disease some have been met with weighing twelve ounces, others weighing scarcely two. Both the increment and the decrement of the natural bulk belong principally, if not altogether, to the outer secreting portion of the gland. If a longitudinal section of the exaggerated kidney be made, its cortical part is seen to be unduly broad: and the same part is disproportionally narrow when the whole organ is smaller than common. For this reason, in the latter case, the radiating medullary portions or pyramids approach nearer to the surface than they are observed to do in a healthy kidney. And it furthermore appears that the enlargement is most commonly coincident with the earlier, and the contraction or shrinking with the later, stages of the renal disease.

The *consistence* of the diseased gland is variable also. Sometimes, and for the most part I believe in the earlier periods, it is soft and flabby: sometimes, and especially in the later periods, it is remarkably compact and hard. The size and the consistence of the kidney are, in most cases, inversely proportional to each other.

Again, the *form* of the kidney, in the disease or diseases in question, often undergoes some modification. As the structural change proceeds, the exterior of the gland shows a tendency to become indented by linear depressions, and to present a lobular shape. This, however, is by no means a constant phenomenon, even in the most advanced stage of the malady.

The proper investing tunic of the kidney is generally stripped off with ease from the large and softer varieties; with difficulty from the contracted and harder. When it has been removed—and less distinctly *through* the same tunic, before its separation—the surface of the gland appears mottled, marbled, or stained; of a yellowish grey colour in one place, and of a dark or purple tint in another. Occasionally it is pale throughout its whole extent; more commonly of divers hues, and variegated with little streaks, which are portions of vessels containing red blood. Sometimes the surface is curiously speckled; often uneven, as if strewed with prominent grains; in some instances quite rough and scabrous; in others perfectly level and smooth. I may add, that when the surface is granular, the kidney very frequently is contracted and small; when smooth, it is usually larger than natural. These several unnatural appearances are generally the more conspicuous, in proportion as the complaint is the more advanced.

FIG. 167.

FIG. 168.

FIG. 167.—Granular degeneration, in its incipient stage.

FIG. 168.—Cortical part of a very granular kidney, containing very numerous microscopic cysts. The tubes are very much degenerated and broken up. Two Malpighian bodies are shown.

The most uniform, however, and the most characteristic of the morbid appearances, are those presented by the cut surface of the kidney, when it has been divided into two symmetrical portions by a longitudinal incision. We then perceive that the cortical substance is the main seat of the morbid alteration. It has lost, in a greater or less degree, its proper red colour and uniform aspect. Sometimes it puts on a speckled or granular appearance; but this, in my experience, is less common than a

pale, nearly homogeneous surface, somewhat like the section of a parsnep. Its natural striæ are confused or obliterated. The incised surface gives one the notion of some deposit, whereby the original texture of the part is obscured. The blood-vessels seem, many or most of them, to have been emptied by compression, or to be blocked up by yellowish solid matters; while the healthier pyramidal masses belonging to the medullary portion of the kidney are displaced, and pushed aside, or eneroached upon by the same yellowish matter, which sometimes interposes itself between, and opens out, their radiating tubuli. Together with these changes of appearance and structure, I have several times found the veins that emerge from the kidney firmly plugged up by coagula of blood.

In some rare cases the kidney is studded, both on its surface and throughout its interior, with numerous small cysts or cells, containing a thin transparent liquid. These cysts have been inaccurately termed hydatids. It is not at all uncommon to meet with one or two larger cysts of the same kind in this diseased state of the organ.

FIG. 169.

Serous cysts of the kidney. From a preparation in Dr. Gross' cabinet.

It has been made a question whether the various appearances which I have been attempting to describe, and which sensibly differ in degree and combination in different cases, are characteristic of different morbid conditions, or merely of different stages and varieties of the same essential change. Our knowledge of the subject is scarcely sufficient to supply a positive solution of this question. The marked physical differences, obvious to the naked eye, suggest however the strong probability of two or more kinds of degeneration of structure: and this *primâ facie* inference is strengthened, as I will presently explain, by the later revelations of the microscope.

There is still another state of the kidney, very different to the eye from any that I have yet mentioned, but which has been thought, and which I think, to be, in some cases at least, the first stage of all in the disorganizing process. This state, which I referred to when speaking of suppression of urine, may be briefly described in two words—*sanguine congestion*. The whole organ is gorged with blood, which

FIG. 170.

Cysts of the kidney.

FIG. 171.

Cysts of the kidney. External appearance.

sometimes drips freely from it when it is cut open. The kidney is in general large, somewhat flabby, of a deep dark red, even of a chocolate or purplish colour, nearly uniformly diffused, except that the cut surface is usually diversified by still darker tuft-like spots, which have been ascertained to be the Malpighian bodies, turgid with blood. This change from the natural appearance of the kidney is evidently of a recent

FIG. 173.

Hemorrhage into Malpighian capsules compressing the tufts.

kind; and the symptoms that have been observed to belong to it are these:—Fever, preceded often by rigors; uneasiness or dull pain in the loins; nausea and vomiting; a very scanty secretion of urine, which is sometimes tinged with blood, and always albuminous; occasionally complete suppression of urine. To these symptoms there is presently added, in most cases, sudden and general anasarca—what is commonly called inflammatory, active, or febrile dropsy. If the secretion of urine be entirely suspended, death soon ensues by coma, as I explained to you yesterday; but if not, the disorder frequently proves fatal through the supervention of some acute internal inflammation; pleurisy, or pericarditis, or pneumonia, or peritonitis. Many persons recover completely from the condition expressed by this combination of phenomena. Many seem to recover, but bear about with them the germs or beginnings of those more chronic and latent changes which constitute one form at least of “Bright’s kidney.”

And what are the signs which indicate, to an instructed eye, the presence of those changes? Some of them are precisely the same, in kind, as those which denote the acuter disorder; only mitigated in degree, and of slower march and succession. The patients are subject to obscure lumbar pains, though these seem rare; to sickness

from time to time, and retching; and their urine is apt to be red, brown, or dingy, as well as albuminous, from the intermixture of some of the colouring matter of the blood. They are obnoxious to inflammations of the serous membranes also; and more particularly to head affections, of which, often, they die; drowsiness, convulsions, apoplexy. And, to finish the resemblance, many of them, aye most of them, become sooner or later anasarca. Besides these symptoms there are others which are not seen in the acute and recent malady; because it is recent. Gradually increasing pallor is almost constant; disease of the heart is common; and the skin, in general, even in the absence of fever, is remarkably dry and unperspiring. The patients are troubled by a frequent want to make water, especially at night, when they are in the horizontal posture; by flatulence of the stomach and intestines; and by caprice of the bowels, which are sometimes obstinately costive, sometimes prone to diarrhoea.

Now it is worth your while to remark, with respect to this category of symptoms, that (nocturnal micturition and the state of the urine excepted) they have no special *primâ facie* reference to renal disease. They are all common enough in various other complaints. In truth they are mere secondary consequences of Bright's disease; and in so far as they are symptoms of it, they are *indirect* symptoms. Before Dr. Bright, no one perceived, in such symptoms, any indications of disease of the kidney. The primary and fundamental organic malady reveals itself by no direct signals excepting those which are furnished by the urine.

Seeing then, that this structural disease of the kidney is coupled with effects so grave and perilous, and seeing that one of its most positive and distinctive marks is an albuminous state of the urine, two questions of great interest at once present themselves.

1. Does albuminous urine *always* imply the presence of Bright's disease?

2. Is Bright's disease, when present, *always* accompanied by albuminous urine?

To both these questions the answer is — no.

I believe that some articles of food, and some medicines, have the effect, in some persons, of rendering the urine for a time albuminous: perhaps it would be more correct to say that certain forms of indigestion may cause this change. Albumen has also been detected in the urine after a blister upon the skin, or under that general state of irritation of the surface, called *eczema rubrum*, which is produced occasionally by mercury. In the crisis of some febrile disorders, in some cases of pregnancy, of heart disease, and of delirium tremens, and in epidemic cholera, the same phenomenon has been observed. Whenever blood, proceeding from any part of the long tract of mucous membrane which lines the urinary organs, mingles with the urine, that fluid of necessity contains albumen, and coagulates if tested by heat or by nitric acid.

On the other hand, when the kidney is really affected in the way already described, the admixture of albumen with the urine is apt to disappear, for a while, even suddenly. I have known it vanish for several hours, immediately after the effectual application of a hot air-bath; and after profuse purging by a full dose of calaterium. Sometimes it is absent for a longer period.

Another important question, therefore, now arises. Finding albumen in the urine, how are we to know whether it does, or does not, indicate the presence of Bright's kidney?

We may judge, in part, by frequently testing the urine, and noticing whether the albuminous impregnation be transitory or persistent. If, week after week, it remain steadily present, it is almost surely indicative of that renal disease. *Almost surely* I say, because it is held by M. Rayer, and though not improbable by Dr. Owen Rees, that uric acid crystals, occurring in the urine of gouty persons, may sometimes, by irritating the urinary tubules, give rise to enduring albuminuria, when there is no degeneration of the kidney. Certain it is that in a very few cases, albuminuria goes on even for years without any serious inconvenience to the patient, or much visible impairment of his general health. If M. Rayer's pathological doctrine be true at all, it probably is true in these cases of abiding albuminuria; and in such cases the albumen will readily disappear under alkaline treatment, which forms a test of their nature. Partly, again, we form our judgment by the absolute amount of the albumen in a given measure of urine. If the water be deeply charged with that unnatural ingredient, the presumption is strong that the kidney disease is in progress; and when that disease is confirmed, another remarkable change is found to have taken place in

the urine. Its specific gravity is very low; and strikingly in contrast with that of diabetic urine. This is therefore a very cogent additional diagnostic circumstance.

On Dr. Prout's authority we have assumed the specific gravity of healthy urine to range between 1015 and 1025. Other writers make it higher. But the urine voided in Bright's disease is sometimes as low as 1004; and its mean specific gravity does not exceed 1013.

I need scarcely again remind you, that the question of specific gravity must always be viewed in relation to the absolute quantity of urine secreted. The specific gravity depends, of course, upon the proportion of the solid constituents of the urine contained in a given quantity. If the aqueous portion be augmented, the effect upon the absolute density will be the same as if the solid contents were proportionally diminished. But when, as frequently happens in certain stages of this renal disease, the specific gravity decreases while the quantity of the urine decreases also, that conjunction of phenomena becomes especially significant.

The density of the urine being thus unnaturally low, notwithstanding the addition of the new substance, albumen, it follows, as a matter of inference, that the solid constituents proper to healthy urine must be sensibly diminished: and they are found, in fact, to be so. These solid ingredients consist mainly of urea, and of certain salts. The aggregate solid contents amount, in health, to sixty-seven or sixty-eight parts in every 1000. In Bright's disease the quantity has been ascertained to have sunk to twelve or fourteen parts; and even, in an extreme case, to less than this — to about six parts.

The urine contains, then, albumen; and it is deficient in urea. These two facts suggested, naturally enough, to M. Solon, and to others, the notion that the albumen might be formed, by a sort of conversion, at the expense of the urea; since these substances, by a slight alteration in the ratio of their elements, pass respectively each into the other. But it is not so. Dr. Christison had observed many years ago, that when the urine was deprived of the greater part of its urea, the quantity of albumen contained in it was small; and, on the other hand, in cases where the urea was considerable in quantity, the albumen was plentiful also. In a more recent work on this subject, the same physician states that the whole of his subsequent experience has been in conformity with this observation.

It being certain, therefore, that the albumen is not vicarious of the urea, what (you may ask) becomes of the urea? It is detained in the blood; and may readily be recognized there in considerable quantity: and herein lies, as I conceive, the secret of the secondary affections which belong to this disorder, and of its great fatality. The body is poisoned in detail by the retention of its own excrements. The blood not being duly purified through that great emunctory, the kidneys, is spoiled for its purpose of nutrition. Besides containing urea, it undergoes other and more manifest changes. Its proportion of fibrin varies; and it gradually becomes poor in colouring matter; the serum is less albuminous also, and of a lower specific gravity than in health. The quantity of albumen in healthy blood averages from sixty-five to sixty-nine parts in 1000. In this malady Dr. Babington has found it reduced to sixteen parts. The average specific gravity of healthy serum is 1028; but in Bright's disease it descends to 1024, 1020, and even to 1013. Now Dr. Christison has made out the very interesting fact, that there is a definite inverse ratio between the coagulability of the urine, and the density of the serum. The more albumen there is in the former of these fluids, the less is there in the latter, and the lower is its specific gravity. So that the deficiencies of the one fluid balance the superfluities of the other. All this is very different from what takes place in diabetes, in which sugar is excreted with urine that is otherwise healthy; whereas, in Bright's disease, urea, which ought to be discharged, remains in the blood; and albumen, which ought not to be separated, is taken from the blood and carried out with the urine.

I have now described the changes exhibited to the naked eye by the kidneys in this disorder, the symptoms which attend it, and the morbid conditions both of the urine and of the blood. But these all vary and fluctuate at different periods of the complaint. I must next, therefore, endeavour to state what has been ascertained of its course and progress.

When the chronic disorder is not a legacy left by the more severe and acute form of disease which I have termed febrile dropsy, it is apt to creep on very insidiously,

and to escape our notice : and its history is not yet fully known. It will be enough if I distinguish two stages of the malady—the early, and the advanced.

In the early stage the urine is generally scanty. Instead of about 40 ounces in the twenty-four hours, the patient voids 16, 12, 8, or even so little as 2 or 3 ounces. Sometimes the secretion is nearly or quite suppressed : and then the head seldom fails to become affected in the way already described. The urine has also an unnatural appearance. It is red, or dark, obscurely turbid, like muddy beer. Smoky, is an epithet frequently applied to it : that is, it looks, sometimes, as if a very minute quantity of soot had given it a tinge. The hue depends upon the presence of a little of the colouring matter of the blood, darkened by the acid properties of the urine. It froths also more than is usual. If you blow into it through a tube, you raise bubbles similar to those which may be formed on soapy water ; and the bubbles remain long unbroken. Its specific gravity is somewhat, yet not greatly reduced ; about 1021, perhaps ; it is seldom at this period so low as 1016. It contains an abundance of albumen. Very rarely does it deposit the lithates.

FIG. 174.

Drawing of red deposit from urine in intense renal hyperæmia.

At the same early period, blood drawn from the arm exhibits the buffy coat. The serum is much diminished in density, and contains a considerable quantity of uræa. There is no decrease in the fibrin ; perhaps it is a little augmented : and there is no great change in the amount of colouring matter.

In the more advanced stages of the disease, the quantity of urine is frequently not below the standard of health ; and it sometimes considerably exceeds that standard, so as to constitute one variety of chronic diuresis (*anazoturia*), which some call diabetes insipidus. It is usually pale, clear or slightly opaque, and of a very low specific gravity ; 1014, 1010, 1007. Once, when the quantity of the urine was *not* in excess, Dr. Christison found the specific gravity to be no more than 1004. There is a corresponding reduction in the natural solid ingredients of the urine. Albumen, too, is present, but more uncertainly than in the early periods : fluctuations in this respect are more common than before. It is a mistake to suppose that the amount of albumen increases as the disorder advances. The contrary rule would be more near the truth. In general the albumen is plentiful and almost constant in the outset of the malady ; less surely present as it proceeds ; and sometimes entirely absent in its latter periods : and it is of importance to remark that the alteration in the specific gravity follows the opposite law. The declension of density, so far from being corrected, augments with the progress of the disorder. Hence the one of these morbid phenomena is a valuable check upon the other, considered as an index of what is going on in the kidney.

And another fact, which it is essential for you to know and to remember, is, that, in any stage of the disease, the supervention of febrile disturbance, from local inflammation or whatever other cause, tends to renew, for the time, those qualities of the urine which belong to the early period.

Meanwhile, the disease advancing, the serum of the blood recovers more or less its lost specific gravity, in proportion to the decrease of albumen in the urine. The quantity of fibrin seems, in some cases, to diminish. But the striking and most characteristic change is the rapid disappearance of the colouring matter, the hemato-sin, as it is called. This may at length be so much reduced, as to form less than a third of the healthy average. If venæsection be occasionally employed, this process of depravation is accelerated; but it takes place whether blood be artificially withdrawn from the system or not. "I am acquainted (says Dr. Christison) with no natural disease, at least of a chronic nature, which so closely approaches hæmorrhage in its power of impoverishing the red particles of the blood." Hence the peculiar pallid or dingy hue of the patient's skin; the leuco-phlegmatic and even waxy aspect which invariably stamps the victims of this complaint.

These characters, then, of the urine and of the blood, when rightly compared and interpreted, reveal not only the existence of the renal disease, but also, with much probability, the stage or degree that it has reached.

Let us next review, a little more in detail, those secondary affections which I have already pointed out as being incidental to the subjects of this renal malady. They are of much consequence: for, in the course of the disease, more or fewer of them are almost sure to occur; most of them are productive of very serious distress: and some of them place the patient's life in immediate jeopardy, and often bring it to a premature end. Moreover, it is by these secondary affections that our suspicion of the primary disease upon which they depend is, in general, first awakened: and it is to the prevention or the removal of these same secondary affections that our curative endeavours must chiefly be directed.

The most common, and practically the most important, of them all, is anasarca; but of this, though I mention it first, I shall postpone, for a while, the further consideration.

Another very common, and very important secondary complication, is the occurrence of what we compendiously called *head-symptoms*: various manifestations of derangement in the cerebral functions: headache, misty vision, noises in the ears, drowsiness, delirium, epileptic seizures, apoplexy. So frequently indeed is the death of the patient preceded by coma, with or without convulsions, that Dr. Christison considers this to be the "natural termination" of the disease, or "the mode in which it proves fatal when life is not cut short by some other incidental or secondary affection." Of seventy fatal cases observed by Dr. Bright, death was ushered in by well-marked cerebral symptoms in thirty.

I have already told you the circumstances under which these affections of the brain usually arise. They almost always follow any great and sudden diminution, or the entire suspension, of the secretion of urine. But this rule is not so strict as to admit of no exception. Occasionally, but I believe very seldom, the urine, in this disorder, is reduced to a very small amount, while the head remains undisturbed. Of this Dr. Christison has recorded a remarkable instance. One of his patients voided no more than two ounces of light urine daily, for nine days before his death; yet he continued sensible to the very last minute of his existence, and died simply of inanition. Sometimes apoplectic symptoms occur, and carry the patient off, although there has been no extreme or material reduction in the quantity of urine.

If the secretion of urine become again abundant, these head-symptoms are mitigated or cease.

Now when death has thus taken place in the way of coma, and the case had been complicated with anasarca, and serous liquid is found accumulated in unnatural measure in the cerebral ventricles, or in the tissue of the pia mater, it seems reasonable to ascribe the coma to the presence and the pressure of that liquid. The dropsy has extended to the brain. And this view of the matter is strengthened by the connexion which may sometimes be noticed between the accession of coma and the visible increase of the dropsy in other parts of the body. My own experience accords entirely with that of Dr. Christison, as expressed in the following statement. "If the dropsical fluid be allowed greatly to accumulate, drowsiness, the first symptom of the affection of the head, very soon makes its appearance in the generality of cases, and it will speedily pass into fatal coma if not controlled, but the removal of the dropsy will usually remove the drowsiness."

To many cases, however, this explanation will not apply, there being no morbid collection of water within the skull, nor any other appreciable change there; nor, perhaps, any dropsy elsewhere. In such cases the ultimate symptoms, the stupor and the death, used to be ascribed to the poisonous influence of the urea in the unpurified blood, upon the organs of animal life. Yet this explanation had its difficulties. Urea must often circulate with the blood without affecting the brain. Dr. Christison states that he has repeatedly known the daily discharge of the solids of the urine to be reduced, for weeks together, to one-fourth of the natural amount, while, moreover, analysis of the blood showed that it was loaded with urea, without the appearance of any head-symptom. Dr. Bright also relates a case to the same purpose. A person labouring under this disease of the kidney lived for four or five years under his occasional observation. The blood was analyzed in the earlier stage, and found to contain a large quantity of urea; as much as the urine itself contained. Yet this patient had no *fits* till towards the close of his life. Urea has even been injected in considerable quantity into the veins of living animals, without any other effect than an increased secretion of urine. Dr. Bence Jones believes that urea is "probably not much more poisonous than nitrate of potash."

The doctrine, therefore, of the dependance of the head-symptoms upon the retention of urea in the blood, *as urea*, has been abandoned by most pathologists, both in this country and abroad. Frerichs, a German physician, who has written an able "monograph" on Bright's disease, offers a new and plausible theory of these nervous complications. The symptoms in question result, he says, from the poisonous agency, not of the retained urea itself, but of the carbonate of ammonia, into which, while still in the blood-vessels, it is liable to be converted. He produced similar symptoms in animals by injecting a solution of carbonate of ammonia into their veins. So long as the peculiar symptoms continue, whether in the sick man, or in the animal subjected to experiment, the expired breath is tainted, he affirms, with an ammoniacal or urinous odour. Reddened litmus paper, held before the mouth or nostrils, is turned blue; and a glass rod, dipped in hydrochloric acid, and exposed to the issuing breath, is presently surrounded with a whitish cloud. When no ammonia can thus be detected in the breath, the nervous symptoms cease.

I have sometimes fancied that the pale and watery condition to which the blood is at last reduced, may have something to do with the stupor and coma. I showed you some time ago, when speaking of spurious hydrocephalus, that similar symptoms are apt to ensue, in conjunction with a similar defect of hematosin. It would seem that, under such circumstances, the functions of the brain are exercised irregularly, languidly, and at length not at all, in consequence of the failing supply of its appropriate stimulus through the arteries.

Another striking circumstance observable in this disease, is a readiness of various organs of the body to inflame, and particularly of the serous and the mucous membranes. According to M. Solon, who has published a thick volume on *Albuminurie*, this disposition has not been so manifest in France; but of its frequent appearance in this country I can add my own testimony to that of Dr. Bright, of Dr. Christison, and of Dr. Gregory. Such intercurrent acute inflammation is not an uncommon cause of the patient's death. The pleura appears to be much more often affected in this manner than either the peritoneum or the pericardium.

Bronchial irritation is exceedingly common. Dr. Wilks, drawing his conclusions from a very extensive observation of cases, remarks of bronchitis, "I am not sure, if all the symptoms were numerically taken, this would not be more universal than any other single symptom, albuminous urine alone excepted."

Disorder of the stomach and bowels is another frequent companion of the renal malady: nausea, vomiting, flatulent distension, diarrhoea. Frerichs observes that in the later stages of the disease, the matters vomited — and the perspiration, when any occurs, which is seldom — are ammoniacal.

It is a plausible explanation, therefore, of these affections of the mucous surfaces, that they are excited by the poisonous material retained in the blood, and seeking a vent through supplementary channels of excretion.

From this tendency, it follows that when we come to inspect the dead body, we seldom find the kidney to be the only part in which structural changes are plainly visible. Most commonly evident traces of disease are met with in various organs.

It would appear, however, that these incidental and secondary complications prevail with irregular frequency in different places. They are probably determined, in some measure, by local and peculiar agencies. Thus vomiting and diarrhoea have been more familiar to the Edinburgh observers, than in London to Dr. Bright, or in Paris to M. Solon: while the headaches and coma, so often witnessed by the British physicians, have been comparatively uncommon in France.

Disease of the heart, if not a secondary consequence, is a very frequent accompaniment of Bright's kidney. It is possible that the cardiac disease, and the renal disease, have sometimes no connexion in respect of cause and effect, but are both results of some common cause; of habitual intemperance, for example.

I am, however, of opinion, that the renal malady has a direct tendency, by its effect upon the blood, to generate disease of the heart. It induces anæmia: and anæmia, as I showed you on a former occasion, implies debility of the muscular texture of the heart, and leads to dilatation of its cavities; and the weak muscle, becoming irritable also, grows thicker as it labours more. But there is another probable cause in operation. Dr. Bright originally suggested that the altered quality of the blood might "so affect the minute and capillary circulation as to render greater action necessary to force the blood through the distant subdivisions of the muscular system." This view of the matter is fully adopted by Dr. Johnson, who points out the probability of "impeded circulation through the systemic capillaries, consequent upon the retention of the urinary constituents in the blood, similar to that which Dr. Reid detected by the hæmadynamometer when black unaërated blood was circulating through the arteries and the systemic capillaries of animals" dying of strangulation. I remember hearing Mr. Paget say that in cases of dropsy from renal disease, attended with hypertrophy of the left ventricle of the heart, he had found *all* the arteries enlarged without being thickened—his attention having been first drawn to that fact by his having noticed that the lower part of the aorta and the common iliacs were large in such cases, and that the external iliacs especially were large and contorted: whereas he had not seen this condition of the arteries associated with hypertrophy of the left ventricle dependent on disease of the aortic valves. Now it is this kind of cardiac disease which, more than any other, has been found coincident with the peculiar changes in the kidney. Among 100 cases, recorded in a tabular form by Dr. Bright, there were 27 in which no affection of the heart could be detected. In 52 instances the heart presented the characters of hypertrophy, and of those no fewer than 34 were free from any trace of valvular disease. Among the 34 there were 11 cases of disease affecting the aorta: in the remaining 23 no cause for the existing hypertrophy and dilatation could be found in the heart itself, or in the great blood-vessels. The true cause may therefore be reasonably supposed to have been the renal disease, operating upon the involuntary muscle through the morbid qualities of the blood.

Dr. Kirkes has recently borne his testimony also to the frequent coincidence of disease in the coats of the aorta with Bright's kidney: and he attributes the arterial change to the excessive force with which the blood is driven into the aorta by the hypertrophied left ventricle, a force unchecked by any valvular disease. "The arterial blood (he observes) is under the continual influence of two unnaturally great causes of pressure, excessive ventricular impulse at one end, and impeded capillary current at the other; and it can scarcely be expected that the walls of the vessels should escape over-distension, and consequent liability to structural change."

Whether the renal disease be ever produced by the cardiac, is more questionable. In the acute renal affection, when it proves early fatal, the kidney is always found to be gorged with blood. And the customary intermixture of blood with the urine warrants the belief that the same condition was present to the patients who have recovered. From this state of engorgement springs, apparently, sometimes, the subsequent series of changes. It is therefore a plausible conjecture that whatever tends to produce congestion of the kidney, tends also to aggravate, and may even cause, the peculiar changes in question. I need not now tell you that disease of the heart does frequently occasion congestion of the venous system, and gorge the viscera with blood. Under this influence the liver often *enlarges*. On the other hand, disease of the heart, even such as gives rise to venous congestion and to dropsy, often lasts long, and proves ultimately fatal, without the occurrence of albuminous urine, and without any appreciable change of structure in the kidney.

Pain or tenderness of the loins, is sometimes, but in my experience rarely, an accompaniment of the renal disease. It occurred, however, in one-third of twenty-eight cases narrated by M. Solon, and Dr. Gregory noticed it in the half of his patients. This symptom appears to be more often present in the early than in the later stages of the malady.

The *causes* of the disease of which I have been endeavouring to sketch the outline, are often obscure. Its more obvious symptoms, in the chronic form of the malady, have been observed, in very many instances, to begin soon after the exposure of the body to wet and cold under unfavourable circumstances. But it is by no means certain—indeed the probabilities preponderate on the other side—that, in these instances, the renal disorder had not previously existed in a latent state.

It is certain, however, that the acute kidney affection, which may be considered identical with febrile dropsy, does often arise under similar circumstances of exposure, and is attended with a marked disturbance of the functions of the kidneys. And Bright's disease in its chronic form has been noticed as occurring in persons who have previously suffered, and had apparently recovered from, an attack of febrile dropsy. Are we not warranted in believing that the recovery was *imperfect* in such cases? that the kidney had sustained irretrievable injury? and that the disease, although from the treatment employed, or by lapse of time, it had become tranquil or latent, was ready again to give indications of its existence upon any repetition of its exciting cause?

Again, it is matter of common observation that intemperate habits have often preceded the development of this disease. Yet we may conclude that intemperance in drinking is rather a predisposing than an essential cause, from the fact that the malady is not unknown among children, and other persons whose manner of life has been strictly sober. I had lately an example of this in a young girl, fifteen years old, who had never menstruated. And this leads me to remark that the renal disorder has been known, in many instances, to follow a sudden check or suppression of the catamenia. It has sometimes seemed to owe its origin to blows received upon the loins.

The complaint happens at all ages: less often, however, in extreme youth than afterwards. Sabbatier records that he saw, while in the service of M. Baudeloque, a young infant affected with anasarca and albuminous urine. The first case described by M. Solon is that of an infant, seventeen months old, in whom similar symptoms appeared shortly after exposure to cold and wet. In 1838 a boy between five and six years old, anasarcaous, and passing bloody and albuminous urine, was in the Middlesex Hospital, under the charge of my colleague Dr. Wilson. M. Constant, in the *Gazette Médicale* for 1835, cites the case of a child five years of age: and M. Rayer gives two plates, representing the kidneys of two children, the one five and the other six years old, who both died of dropsy with albuminous urine, the sequel of scarlet fever. In each of these the changes described by Dr. Bright were well marked, and the bulk of the kidney was considerably increased.

The malady is, however, much more common in adults: not, in all probability, because the kidney is more readily susceptible of it at one period of life than another, but because, as life advances, the circumstances which tend to produce or to foster it become of more frequent operation; intemperance, exposure to great vicissitudes of temperature, and (perhaps) disease of the heart.

It occurs, I presume for the same reasons, oftener in men than in women.

Dr. Christison suspects that Bright's kidney happens chiefly in persons of scrofulous habit; and he found it, in several instances, coincident with phthisis pulmonalis. My own experience would not have led me to that opinion. I partake in M. Solon's doubts, whether the co-existence of pulmonary consumption and of this renal malady is more than casual. Dr. Bright tells us that "the instances in which phthisis, or any form of scrofulous or tubercular disease, has been connected with the renal affection, have been decidedly rare."

What, after all, is the true character and essence of the organic metamorphosis which constitutes this formidable disorder, Bright's kidney? Since I last spoke upon this subject our knowledge has made several steps in advance. On former occasions I have expressed to you my belief that some of the grosser changes of structure ascertained by the ordinary mode of inspection, were ultimately owing to an undue accumu-

lation of blood in the renal vessels; to congestion—passive or inflammatory. And to this conclusion, which observation and reasoning had suggested, direct experiment lends strength. In this way it has been shown, by Dr. George Robinson, that a mechanical impediment to the venous circulation in the kidney, whether it be partial or absolute, whether rapidly effected or slowly, is sufficient to produce albuminous and even bloody urine. Rayer calls the complaint *albuminous nephritis*; and perhaps the congestion (which unquestionably is present in what I consider the acute form of the malady) may sometimes pass into chronic inflammation. We do not, however, find that it ever terminates in decided abscess: yet suppuraction of that kind is no uncommon event of true inflammation of that part, excited by violent injuries, or by the lodgment of calculi within it. It seemed to me more probable that, in one form at least of the disorder, the mischief done to the kidney was the result of extreme congestion, and its usual consequences—the oozing forth of the blood in substance, or of some of its constituents, into the interstitial textures, as well as into the excretory tubes of the kidney. The appearance of these ingredients of the blood, and even sometimes of blood itself, in the urine; the increased size of the gland in the earlier stages; the various shades of colour which its surface and parts of its interior present, as the colouring matters of the effused fluids are more or less absorbed; the impermeability of those altered parts by artificial injections; the shrinking (in many cases) and hardness of the organ as the disorder becomes chronic, and absorption proceeds; these are all consistent with this theory. The morbid conditions of the urine depend, in part, upon the mechanical transudation of certain portions of the blood, which pass through the kidney unchanged, as through an inert filter. Mixed with the urine we find serum, with its albumen, and its salts, which diminish the acidity of the mixture, or even render it neutral; and in many cases we find more or less of the colouring matter also of the blood. Those portions of the extravasated fluid which have no outlet of escape, solidify, and thus obliterate the natural texture of the part they have invaded. The obstruction of the emergent veins of the kidney by firm clots of blood is in harmony with the same supposition.

But more has been learned than this. New light has been thrown, of late years, upon the doubtful pathology of this important and complex renal affection, by that minute scrutiny of texture and of textural changes, as well as of conditions of the urine, which the microscope perfects or facilitates. Yet I have not the satisfaction of being able to tell you that the interesting problem has been finally solved. Though 30 years have passed away since Dr. Bright announced the dependence of certain forms of dropsy upon structural disease of the kidneys, it still remains a disputed point among pathologists whether “Bright’s kidney” is one disease, assuming different

FIG. 175.

aspects in different cases and circumstances, or whether there are not two, or even more, distinct renal diseases which, giving rise to similar symptoms, have been comprehended and confounded under one common name.

Fig. 177.

their condition, when life is not destroyed. And I must tell you that death in this form or stage of the renal disease is a comparatively rare event. In 20 instances only out of 292 cases observed or collected by Frerichs, were the kidneys in this first stage—the stage of inflammatory congestion. This renal derangement is often completely recovered from: but doubtless it also forms, in many instances, the starting-point of the more chronic phases of Bright's kidney. Frerichs, Reinhardt, and other German writers hold that it is so in *all* cases; that all the renal changes to which that name is applicable, are only successive stages of one morbid process. Calling this the first, they describe a second and a third stage.

In the second of these alleged stages, the kidney is still much larger and heavier than is natural, and smooth on its surface; but the sanguine congestion is diminished, or gone; while the inflammatory exudation into and among the proper tissues of the gland is great and manifest. This exudation, by its presence and its pressure within and around the tubules, empties the capillary vessels of their blood, and keeps them empty. The cortical portion of the kidney, still unduly broad, loses its red colour, becomes pale or yellowish, and contrasts more strongly with the red lines of the pyra-

All agree in opinion about that condition of the kidney which has been ascertained to exist in what is called inflammatory dropsy; and in the dropsy which not unfrequently occurs during convalescence from scarlet fever. That condition I have already described. The kidney is large, soft, red, and bloody. But something more requires to be said respecting the phenomena presented by the urine in such cases. Not only is it always albuminous; and often dingy in colour, and sometimes even reddish, from an admixture of blood; but it is found, when examined through a microscope, to contain a number of little hair-like threads or cylinders, which are, in fact, very slender fibrinous coagula, moulded in and discharged from the urinary tubules of the kidney. These cylinders or casts denote, even more distinctly than any amount of albumen in the urine denotes, extreme congestion, which may well be deemed inflammatory, in the affected kidney. They are commonly studded with minute epithelial cells, which have been detached from the surface of the tubules. Sometimes they contain blood disks also, and even specks of lithic or oxalic acid. By the help of the microscope similar casts may be seen still remaining in many of the tubules. Other tubules appear to be filled with epithelial cells which have been shed from their walls. And similar cells are scattered separately through the urine.

These are the anatomical characters of what Dr. Johnson calls *acute desquamative nephritis*.

Such, then, is found to be the condition of the kidneys in fatal cases of this kind; and such we may safely infer from observation of the symptoms and of the urine, to be

The figures from 176 to 179 inclusive, are intended to illustrate the changes observed in the enlarged form of degenerated kidney.

FIG. 179.—Microscopic view of epithelium-cells and fibrinous shreds from the tubuli uriniferi of a kidney affected with Bright's disease. (1) Epithelium-cells from the tubuli uriniferi, loaded with oil-globules, magnified 400 diameters. (2) Fibrinous shreds from their interior, having blood-corpuscles and oil-globules entangled in them, magnified 200 diameters. (3) One of the tubuli from a kidney affected with Bright's disease. Oil-globules are seen through its walls.

midal bodies. Gradually the matters exuded suffer further change, and sometimes undergo a fatty degeneration. The tubules lose their uniform cylindrical shape, and bulge a little here and there: their epithelial cells enlarge, become opaque, contain granular matter, and perhaps oil globules: finally, they crumble down, and are partly washed away with the aqueous portion of the urine which proceeds from the Malpighian capsules.

That this is a faithful picture, drawn from nature, I make no question. That it represents a further stage of the condition previously spoken of, as the effect of inflammatory congestion, is less certain, though very probable. That it is a transition stage, towards what I shall presently describe as the third stage of the German writers, is in my judgment more than doubtful. It seems to be identical with the result of what Dr. Johnson calls chronic non-desquamative nephritis. In the common parlance of English physicians it is *the large white kidney*.

This state is much more often met with in the dead body than the former. It characterized 139 of the 292 cases of diseased kidney already mentioned.

The third stage is the stage of absorption. The kidney is contracted and small. Its surface is irregular, rough, knobby; its substance firm and tough. Its capsule is detached with difficulty. The cortical substance is unduly narrow. Some of the tubules, from which the casts and epithelial cells have been washed away, are collapsed and atrophied. Those which remain full, project; and give a granular aspect to the outside of the gland as well as to its cut surface. This is the issue, in Dr. Johnson's classification, of chronic desquamative nephritis. We speak of it familiarly as *the small contracted kidney*.

This also is a form of disease that is frequently seen. It constituted the remaining 133 of Frerichs' 292 cases.

Besides the fibrinous casts already described, in which epithelial cells are commonly entangled, the urine, in Bright's disease, not unfrequently contains tube casts of a whitish or waxy appearance, without any cells, and of comparatively large size; large, because moulded in tubes previously denuded of their epithelial lining. Sometimes similar wax-like casts of smaller diameter are met with, which have come from tubes in a state of wasting and contraction.

Now I shall not attempt to harmonize the fluctuating and conflicting opinions which have been expressed respecting the relations that may subsist between these

FIG. 180.

Epithelial cells in urine.

different appearances and conditions of the kidney. Authentic materials, sufficient for a satisfactory solution of the difficult questions in dispute, have not yet, I think, been collected. In this uncertainty, I can only set before you my own conjectures upon the probabilities of the matter.

It has been objected to the simple and plausible doctrine of the German authors

FIG. 181.

FIG. 181. — Drawing of atrophied kidney.

FIG. 182.

FIG. 182. — Cortical part of a very granular kidney, containing very numerous microscopic cysts. The tubes are very much degenerated and broken up. Two Malpighian bodies are shown.

whom I have cited, that regard being had to symptoms, their second and third stages are often met with when there has been no first stage: and again, that the third occurs without any preceding first or second. To the former part of this objection I attach no great weight: the latter I believe to have more validity. Extreme congestion, nay, inflammatory exudation, may rapidly befall the kidney, and yet escape detection, either by the patient or by his medical attendant, if he has one. Of the two things which would mark its presence most distinctly, one, namely, the sudden anasaric swelling, may be inconsiderable, transient, or perhaps wanting altogether; the other, namely the peculiar condition of the urine, may easily pass without notice, inquiry, or suspicion. Both may, I believe, come and go, without strongly arresting attention, or permanently impressing the memory.

I think it, then, probable, that the second and third stages of the German writers may, both of them, be truly stages or consequences of their first: not, however, *successive* stages, but each a *final* stage. The large white kidney I can conceive to be the result of so much inflammatory exudation,—blocking up or obliterating a great part of its texture—as could never be absorbed down to the size and appearance of the small contracted kidney. In the small contracted kidney I can conceive the stress of the inflammatory disturbance to have fallen mainly upon its free secreting surface, to have operated in spoiling the tubules, in destroying and discharging their epithelial lining, and in wasting the whole apparatus. The one seems to me to have some analogy with the lung which has been enlarged and rendered heavy and solid by hepatization in pneumonia:—the other with the shrunken lung, which has suffered more or less of collapse during the progress of chronic bronchitis.

Other forms of Bright's disease are spoken of, but I should only puzzle you and myself were I to dwell much upon them. There is the large, firm, *waxy* kidney, which appears to occur chiefly in persons of the scrofulous habit, and to owe its peculiar appearance to the presence of a lardaceous or bacon-like substance blocking up, more or less, and so spoiling, the cortical portion of the gland. I showed you formerly that the liver and the spleen are both of them subject to a similar change of texture. In the kidney the Malpighian tufts, and their small afferent arteries, are the first parts to be invaded. It is probable that this morbid condition arises gradually and insidiously—is chronic from the first—is not necessarily preceded by an acute stage of active or inflammatory congestion. If, in a patient presenting symptoms of Bright's disease, such as dropsy with albuminous urine, you find the liver large, smooth, and

painless under pressure, if there be any palpable tumour of the spleen, if there be any serofulous caries of the bones, and, *a fortiori*, if two or all of these unnatural conditions be coexistent, you have presumptive evidence that the renal change is of the waxy, lardaceous, or albuminous kind: and the presumption will be strengthened if wax-like casts, large or small, of the urinary tubules, are voided with the urine.

Again there is the red *coarse* kidney, which, when not the result of mere mechanical congestion, is probably an earlier state only of the ordinary large white kidney. A similar account may be given, I fancy, of the *mottled* kidney. With any of these changes there may, or there may not, be an admixture of fatty degeneration.

It will be more to the purpose if I direct your attention to certain distinctions, of practical importance, between the two well marked forms so often mentioned, the large white kidney, and the small contracted kidney. In doing this, I shall chiefly follow Dr. Johnson, who has cultivated the whole subject of renal disease with great diligence and success.

It is observed, then, of the large white kidney, that "it never proves fatal without the previous occurrence of dropsy, which is one of its most usual and prominent symptoms; while the small contracted kidney proceeds, in many instances, to its extreme limit of degeneration, and at length destroys its victim without giving rise to dropsy in any form or degree." "The first" (says Dr. Wilks) "invariably kills the patient; the second may be found when death is brought about by other means."

Another remarkable difference between the two, explanatory, indeed, of the difference just stated in respect to dropsy, is that where the large kidney exists, "the urine is almost invariably less copious than in health, and contains a large amount of albumen; whereas the hard contracted kidney furnishes, as a rule, a quantity of urine considerably above the natural standard, which urine also contains much less albumen." The blood is less robbed of its proper albumen, and therefore less impoverished, while its aqueous part is drained plentifully away. Both of these circumstances are adverse to the occurrence of dropsy. But in this form or condition of disease, any sudden check to the quantity of urine is apt to be followed by dropsical effusion, and speedy death.

In correspondence with these differences, it is found, as might be expected, that the specific gravity of the urine proceeding from the large white kidney is notably greater than that from the small contracted kidney. The former is seldom below 1015, and may be as high as 1025 or even 1030. The latter is commonly below 1015, and varies downwards to 1010, or even 1005.

By attending to these external symptoms you may generally decide, in a given case, with which of these two forms of renal degeneration you have to deal, and frame your prognosis accordingly.

When death has occurred, the kidneys present physical differences which help to explain the observed differences in the symptoms. "In that form of disease," says Dr. Johnson, "which leads to the small contracted kidney, the gland cells become disintegrated, detached from the basement membrane, and finally washed out with the urine. The tubes are thus either entirely denuded, or they are found to be lined by a layer of delicate cells, entirely different from the normal epithelium. It is probable that a tube in either of these conditions, while it has lost the power of secreting the solids of the urine, may yet retain that of separating the watery constituents from the blood," and thus may be explained the "abundant flow of urine, pale in colour, and low in density." In the large white kidney, "the gland-cells are never so detached, disintegrated, and swept away as to leave the tubes denuded. They remain adherent to the basement membrane, and undergo changes, varying from a slight granular opacity to a complete oily degeneration, or they become replaced by an albuminous or fibrinous material, which more or less fills the tube." This condition seems to him not so favourable as the former for the transudation of water.

Again, in the large kidney "the number of pervious blood-vessels, if not greater than in the healthy kidney, is rarely in any considerable degree less than normal. In the contracted kidney the opposite condition is found. As the disease advances, many of the uriniferous tubes shrink, and the vessels which supply them—both arteries and Malpighian capillaries—have their canals obstructed, and their walls covered with oil globules, so that the kidney is reduced to the condition of an organ

but scantily supplied with blood; and obviously in the same proportion the materials for a copious secretion of *albumen* are wanting."

I have made no mention of simple fatty degeneration of the kidney, which I believe to be a real but a rare disorder, and which Dr. Johnson was the first to recognize and to describe. It does not, however, appear properly to belong to the class of cases known to us under the comprehensive title of Bright's disease. Dr. Johnson admits that it is sometimes met with, both in the human subject and in the lower animals—in cats and in dogs—unconnected with albuminous urine or with any other functional symptom of renal disease. It is nevertheless a very serious and formidable affection. Its pathological characters are these. The gland is large, but (except in accidental complications) it does not contain any inflammatory or albuminous exudation within its proper texture. In all the tubes of its cortical substance a large quantity of oil is to be seen, which for the most part is enclosed in the epithelial cells.

This change, too, has its analogue in the simple fatty degeneration of the liver. When it is accompanied by albuminous urine I suspect that it will always prove to have been complicated, to a greater or less extent, with one or other of those structural faults which are characteristic of Bright's kidney.

Respecting the origin of the minute vesicles and larger cysts which I mentioned before as being sometimes associated with the other renal changes, there is much discrepancy of opinion. Dr. Johnson believes that they are simply dilatations of the urinary tubules, after those tubules have been denuded of their epithelial lining. Mr. Simon ascribes them to an effusion of cell germs from broken tubules. Certain diseased states tend to block up these tubules: "the obstruction at length produces rupture of the limitary membrane, and then what should have been the intertubular cell-growth continues, with certain modifications, as a parenchymic development." Dr. W. T. Gairdner, again, regards these microscopic cysts as being parasitic, and entirely foreign to the structure of the kidney. He maintains that the attempts to connect them with morbid conditions of the tubuli uriniferi and epithelium, have been founded on imperfect observation. But for further detail on these points I must refer you to Dr. Johnson's book on the *Diseases of the Kidney*: to Mr. Simon's paper in the 30th volume of the *Medico-Chirurgical Transactions*: and to Dr. Gairdner's observations, published in the *Proceedings of the Edinburgh Physiological Society*, in the Session of 1852–53.

The single fact that in Bright's disease both the kidneys are always more or less affected, sufficiently demonstrates that the disorder falls primarily within the category of symmetrical, and therefore of blood disorders. You have seen how the organic changes which arise in the course of that disorder re-act in their turn upon the blood, and operate in further spoiling its natural constitution and properties. Whether the renal mischief results, as Dr. Johnson supposes, from the passage through the kidneys of some specific poison—the poison of scarlatina for example, the poison retained in the blood through suppressed perspiration, or the like—I do not know, and need not here discuss.

We are living in an age when organic chemistry, and microscopic research, are, severally and together, bringing vast and continual accessions to our knowledge both of the essential nature of diseases, and of their rational management. No better instance of this could be adduced than the progress which has recently been made towards unravelling the complex and intricate pathology of "Bright's kidney." That progress I have now endeavoured briefly to set forth; but I must again remind you that towards the full solution of the problem certain steps only have yet been made. Much that I have now been telling you will, doubtless, require to be remodelled hereafter; and not a little, probably, to be corrected.

There is yet something to be said respecting the *dropsy*, which is so common an accompaniment of these renal changes; but I must defer it till to-morrow.

LECTURE LXXIX.

Anasarca ; its consideration resumed. Distinction of chronic General Dropsy into cardiac and renal. Characters and signs of each of these varieties. Treatment.

WE were yesterday occupied with the circumstances of that remarkable malady, which has never received a good, distinctive name, but which is sometimes called *Bright's disease*, after the distinguished living physician who first recognized and described it, sometimes yellow or mottled degeneration of the kidney, sometimes granular degeneration. I endeavoured to represent to you, by words and by drawings, the coarser changes of structure which are visible by the unaided eye in the several stages or forms of the diseased kidney; and I stated some of the results of that minuter insight into its morbid conditions which the microscope has brought within our power. I spoke of the symptoms which appear *essential* to the malady, and which consist in certain striking changes in the urine and in the blood of the patient. I mentioned also the symptoms which are *incidental* to the renal disease. But of one of those incidental symptoms, or secondary consequences, I postponed the full consideration till to-day: I mean the *anasarca*, with which most commonly, yet by no means always or necessarily, it is complicated.

This is, for several reasons, a very important symptom. It is usually the first thing that prompts us to suspect, and to inquire after, the renal malady. It was through his researches into the relation subsisting between chronic dropsy and the conditions of the urine, that Dr. Bright was led to the discovery of the associated affection of the kidney. The dropsical accumulation adds greatly to the patient's distress, and sometimes constitutes nearly the whole of it. It adds proportionally to his danger. Moreover, it is that consequence of the renal disorder over which our curative measures have the most control. Indeed, under this complication we have, practically, to consider the remedies of the dropsy, distinct from the remedies of the renal change.

In most cases, at the outset at least of the dropsy, the skin is dry, and the urine is scanty: and the anasarca is observed to increase, or to decrease, as the quantity of urine diminishes or augments. The aqueous fluid, which should escape from the surface and through the kidneys, collects in the subcutaneous areolar tissue. As the disorder advances, the tendency to effusion of serum through the sides of the blood-vessels is probably increased, not only by the sluggish movement of the blood in the veins, from progressive debility of the heart, but also by one of the causes of that debility, the thin and watery condition of the blood itself; a condition which I yesterday pointed out to you as one of the most uniform and striking effects of the primary disease.

And here I again take up the subject of anasarca and general dropsy. You will remember that, in the early part of the course, I entered somewhat fully into the general pathology of dropsies. At the same time I promised you that I would afterwards, and when you were better prepared to understand them, endeavour more fully to explain some grand distinctions which have been found to exist between different forms of general dropsy. Having now, at last, brought before you all the organic changes which are apt to give rise to anasarca, I am in a position to redeem that promise. In doing so I shall probably have to remind you of some things which you have already heard from me.

Anasarca, you will please to recollect, signifies the filling up of a considerable part, or of the whole, of the subcutaneous areolar tissue, with serous or watery fluid: and when to this is added a collection of liquid in the large serous cavities also, we call the complaint *general dropsy*.

It is obvious that this condition may exist, and in nature it does exist, in various degrees: from slight infiltration of the areolar tissue, scarcely noticeable until, after some hours passed in the upright posture, it accumulates in visible œdema about the ankles—to the other extreme, in which the integuments are everywhere stretched to the utmost, even to bursting; the insteps bulging upwards; the legs and thighs enormously enlarged, cylindrical, unshapely, and exhibiting partial vesications; the sur-

face of the trunk of the body capable of being kneaded and moulded like dough; the skin of the penis distended, and in consequence of its confinement by the frænum, twisted and circumvolved so as materially to impede the outward passage of the urine; the scrotum, as big as a child's head, preventing the miserable patient from bringing his thighs together, and from lying upon either side; the hands swollen; the face and neck bloated. With all this, the peritoneum is generally full of liquid, and at length the pleuræ; and as the scene is about to close, there is water in the ventricles of the brain, or an anasarcaous pia mater.

Now from whatever cause this watery condition of the whole body may arise, the effects resulting from the presence of the water are the same. And of what do patients in this state usually complain? Why of shortness of breath, and palpitation of the heart; of a sense of impending suffocation if they attempt to lie down, or to bestir themselves actively; of tightness and distress across the epigastrium, relieved somewhat by eructation, augmented by food and drink; of weight and stiffness of their limbs; and, sometimes, of drowsiness.

The explanation of all this is easy and obvious. The shortness of breath may be accounted for on various grounds: by œdema of the lungs themselves, a state that is revealed to us through auscultation; by water in the pleuræ; by the pressure upwards of the diaphragm, which embarrasses still more the labouring heart and lungs; and this upward pressure is increased by any kind of distension or repletion of the stomach, diminished when the stomach is collapsed and when the upright position is maintained. The heaviness and want of pliability of the unwieldy limbs are, like the rest of these phenomena, purely mechanical. All parts are oppressed by the unnatural load of water.

But we must look beyond the dropsy: and inquire whether the complaint has set in suddenly, and simultaneously with febrile disturbance, invading all the districts of the body at once, and quickly reaching its present degree; or whether it has crept upon the patient slowly and by stealthy steps: whether it has had any obvious or probable exciting cause: or whether it has approached insidiously, we know not whence or why: whether (in a word) the case be one of active and febrile dropsy, or of chronic and passive.

Now setting aside, for the present, any more particular consideration of the acute or febrile form of general dropsy, and contemplating those forms only which are chronic, we find that all, or nearly all of them, may be arranged in two great classes; those which depend upon disease or debility of the heart forming one class, those which depend upon disease of the kidney constituting the other. To these classes we accordingly apply the terms *cardiac dropsy*, and *renal dropsy*. They are often combined in the same individual; but taking the pure cases of each form, we may proceed to inquire into their peculiar features, how they may be distinguished, and what differences of treatment they may require.

And first of cardiac dropsy.

The mode in which disease of the heart may occasion general dropsy has been sufficiently explained already. We infer that the dropsy, in a given case, has this origin, if we find that thoracic symptoms, such as cough and dyspnoea, preceded the dropsy: or if we perceive direct signs of cardiac disease, such as distended jugular veins, irregular movements of the heart, unnatural impulse, altered sounds: or if we trace the history of some previous acute disease affecting especially the left side of the thorax: or if we learn that the patient has formerly suffered acute rheumatism: or if the patient's age be so much advanced as to make it probable that some of those organic changes in the heart and large blood-vessels are in progress, which are almost natural in the decline of life. And our inference is confirmed if there be no discoverable indication of renal disease.

But we see many persons who labour unequivocally under organic disease of the heart, yet who survive, even for many years, without becoming dropsical. The interesting question therefore arises, of what kind of heart-disease is dropsy a consequence and symptom? You already know the answer. It is such disease as offers a certain amount of permanent obstruction to the passage of the venous blood. Hence dropsy is especially associated with dilatation of the right chambers of the heart. It would not be correct to say that the anasarca is *dependent* on such dilatation, for the dilatation itself is at once an effect and a sign of impeded transmission of blood from

the right side of the organ. Nor is such dilatation a necessary attendant on the general accumulation of water. The impediment may be sufficient to gorge the right cavities, while it is yet to slight in amount, or too recent in duration, to have dilated them.

What, then, are the physical conditions which oppose to the blood in the veins such an impediment as we are now considering? The two great vital organs contained within the thorax, the heart namely and the lungs, form different parts of one common mechanism, the object of which is to supply every tissue of the body with blood that has recently been purified by exposure to the air: and these organs, thus closely related in their functions, are moreover so reciprocally dependent, that structural disease occurring in the one, tends to produce disease, sooner or later, in the other also.

And I wish you again to observe the order and direction in which disease is, almost always, propagated from one part of this apparatus to another. It is a backward direction—opposite, I mean, to the course of the blood. There are, strictly speaking, two hearts, which lie side by side, in respect of their anatomical position, but which, reference being made to their vascular intercommunication, are really separated from each other by the lungs. The great veins precede, the great arteries follow, this chain of connected organs. Disease occurring in any one part of the chain becomes a cause of consecutive disease in the part immediately behind it. And this law obtains, as I have shown you before, in regard to the several chambers of the heart, considered as a single organ.

Thus, structural disease situated at the aortic outlet of the heart, and of such a kind as to hinder the exit of the blood from the left ventricle, gives rise to permanent changes in that ventricle; to hypertrophy with, or less commonly, without, dilatation. The hypertrophy is strictly a compensating and conservative change; and when it is exactly proportioned to, and keeps pace with, the impediment which has given it birth, so as precisely to balance and countervail it, no delay takes place in the stream of arterial blood, and the injury is, as yet, confined to the left ventricle. That chamber is remodelled, and adapted to its purpose by the *vis medicatrix nature*; and no other evil manifests itself than, perhaps, some slight encroachment and pressure upon the neighbouring parts, in consequence of the augmented volume of the heart.

So long as the mitral valve remains healthy and effective, it offers a barrier of protection against the extension of the disease in the direction which is retrograde to the course of the blood. But at length, in most instances, the stress becomes sensible further back. The left auricle and the pulmonary veins become choked and distended; the blood is detained in the lungs. Then commences *dyspnœa*: at first occasional only, whenever the heart is tasked with the conveyance of a greater quantity of blood in a given time than usual, as in brisk movements of the body, or sudden emotions of the mind; or when it is oppressed by circumstances that diminish the capacity of the chest; by a full meal, therefore, by flatulent distension of the stomach and intestines, by the recumbent posture. Afterwards the shortness of breath becomes more or less constant and distressing.

Now this loaded and embarrassed state of the lungs, even when it is permanent and has reached a considerable degree, may exist without materially interfering with the functions of the right or venous heart; for the pulmonary plethora may be relieved by increased secretion from the bronchial mucous membrane. *Dyspnœa*, even when it has become habitual, may precede for some time any appearance of dropsy.

At last, however, the effects of the original evil augmenting and extending, the right ventricle also becomes unable duly to propel its contents into the pulmonary vessels; it continues morbidly full, is first distended occasionally, then permanently, and at length really dilated; and with that dilatation we have a turgid venous system, of which we see a part in the prominent veins of the neck.

In this way, then, may be explained a series of symptoms which you will often witness, and be consulted about, in persons who are growing old. You will find irregularity of the pulse; preternatural impulse perhaps of the heart; occasional shortness of breath; large crepitation, habitually audible in the lower and hind portions of the lungs; more or less expectoration, sometimes tinged, sometimes even loaded, with blood. Eventually the ankles begin to swell; and the patient (if his

life be not cut short earlier in some other way) becomes by degrees decidedly and universally dropsical.

Many of the direct signs of diseased heart may exist, therefore, while there is no anasarca: intermissions and irregularity in its movements, palpitation, the impulse proper to hypertrophy. But when dropsy has supervened, we may expect those signs also which denote dilatation of the right chambers. The heart is heard and felt to beat beyond the præcordial limits; the pulsations become feeble and unequal, if they were not so before; the patient is liable to fluttering palpitations, to extreme and panting dyspnœa on the slightest exertion, even on taking food into the stomach, or adopting the recumbent posture; his skin assumes a dusky hue, and his lips and extremities are apt to be livid.

In these cases the anasarca first becomes manifest about the ankles. During the earlier stages the œdema disappears in the night, and returns towards the next evening. It is sometimes confined, for a long while, to the legs; but ultimately it creeps up towards the trunk of the body; the thighs enlarge, the loins and flanks become doughy, the serotum fills, and water collects in the serous bags of the abdomen and thorax. In extreme cases the dropsy is universal, pervading the areolar tissue of the head and face and upper limbs.

As the accumulation of serous liquid is commonly gradual, the reticular tissue, partly perhaps through maceration, but chiefly from continued pressure and stretching, loses its elasticity; and the œdema is soft, and *pits* readily.

Sometimes, the fluid continuing to increase, the cuticle is raised by it, and large vesications take place on the limbs; or some part of the areolar tissue sloughs, and a breach of surface is made, and the fluid drains off by this vent in great abundance, to the signal relief of the patient. This beneficial accident furnishes us with a valuable practical hint.

Such, then, is the consummation of disease commencing in the left heart, and working its gradual way, through the lungs, to the right heart. But the obstacle may originate at a less distant link in the chain. The circulation may be checked, first of all, in the intermediate lungs: and it may be worth our while to consider, for a moment, the relations which subsist between general dropsy, and certain *pulmonary* diseases.

Whenever, in pneumonia, a large portion of one or of both lungs becomes impervious to air and to blood—or when pleurisy fills one side of the thorax with liquid, which, by its pressure, shuts out both air and blood at once from one-half of the respiratory apparatus—the egress of the blood from the right heart, and, therefore, from the venous system, cannot but be checked. We might expect that dropsical effusion would be the result of these changes; and in truth it does sometimes occur. That it does not happen more frequently is to be attributed, I believe, to the free evacuations and the strict abstinence, which are early put in force in those complaints, and which relieve the venous plethora before it produces effusion.

So, again, lungs that are hollowed out into large cavities, or rendered solid over a wide space by numerous tubercles, are manifestly incapable of admitting into their vessels from the right ventricle the ordinary quantity of venous blood. In these cases, however, the whole mass of blood is diminished, and kept within the limit which does not imply distension of the veins, by the constant agency of various causes: by the imperfect nutrition consequent upon abdominal disease; by the sometimes copious expectoration; by the wasting diarrhœa; by the profuse nocturnal sweats. Accordingly anasarca is an unusual symptom in pulmonary phthisis, or shows itself in the latter periods only of the disease, in the form of œdema of the legs: and its occurrence then is mainly owing to the debility which affects, in common with the other muscular parts of the body, the moving organ of the blood.

The pulmonary disease which more commonly and certainly than any other, though often very slowly, leads to dropsy, is *emphysema* of the lungs. I showed you, some time ago, that in this morbid condition many of the smaller blood-vessels of the lung become gradually obliterated; and when the disease is extensive and advanced, large portions of the organ are visibly white and bloodless. Meanwhile, the nutrition of the body is not impaired; the same quantity of blood continues to be returned towards the heart, but it finds not a ready entrance into the pulmonary blood-vessels, when delivered from the right ventricle. A certain amount of accumulation becomes

habitual in that chamber, and in the great veins; nay, the very cause of the emphysema tends also to dilate the heart; at length the capillary vessels feel the mechanical congestion, and more or less anasarca ensues.

So much for dropsy that is purely cardiac. Let us next consider the circumstances from which, during the lifetime of the patient, we draw the conclusion that the dropsy he exhibits is of renal origin.

There is not much, that I know of, which is very peculiar or distinctive in the characters of the anasarca itself. This however is observable;—that whereas in cardiac dropsy the anasarcaous swelling begins in the lower extremities, in renal dropsy it is often noticed first in the face and in the upper extremities; in the eye-lids, in the cheeks, and upon the backs of the hands. These you will remark are uncovered, and therefore visible parts. I believe that an equal amount of swelling would at the same time be detected, were it looked for, in the feet and ankles. Resulting more than the cardiac variety from an unnatural state of the blood, the watery effusion takes place more suddenly and more universally; from the vessels of every region of the body at once. Cardiac dropsy arises from mere mechanical delay of the blood—and that delay is felt most at the greatest distance from the heart, and in the most depending parts of the body. This early anasarca of the face and hands is the more marked in proportion as the renal disorder is recent and acute; or when, being chronic, local inflammation, or febrile disturbance, is suddenly superadded. According to my experience it is less noticeable when the dropsy comes on slowly and insensibly during the progress of chronic degeneration of the kidney. The more rapid and copious the effusion, the less do the dropsical parts pit upon being pressed. It may be said also of this renal form of dropsy, that accumulation in the larger serous cavities is not, in general, a prominent feature.

If we find, upon due scrutiny, no material or adequate embarrassment of the respiratory functions, no deviation from the natural sounds of the heart, no derangement of its regular movements, no alteration in the force of its pulsations, or in the space over which they can be felt and heard, no distension of the large veins of the neck—then we have strong reason for suspecting that the anasarca is connected with some vice of the kidney.

But we cannot infer, from the *presence* of heart-symptoms, that the kidney is free from disease.

Our judgment is guided, or assisted, in some degree, by the *complexion* of the patient. When general dropsy depends upon disease of the heart, the cheeks and lips are occasionally florid, often purplish or livid, frequently dusky and loaded. Sometimes (as in chlorotic women, where the heart may be temporarily distended without any positive organic disease, and the blood is thin and poor) the face and mucous membranes are pale: but in the renal variety of dropsy there is a very characteristic hue; an evident lack of red blood, indeed, in the capillaries, but withal an unhealthy dingy sallowness, significant, to a practised eye, of some deep-seated alteration of structure.

Our suspicion that the kidney is the organ primarily in fault is strengthened, if we trace certain accidents in the history of our patient. An attack, for example, of illness, attended, perhaps, with temporary swelling of the body and disturbance of the urinary functions (acute dropsy, in short), soon after some exposure, under unfavourable circumstances, to the influence of cold; either applied to the external surface, or to the stomach by a draught of cold drink. Or, a similar though transient anasarcaous condition, which came on during convalescence from scarlet fever. For, as I told you yesterday, there is reason to believe that in *acute* dropsy is often laid the foundation of those peculiar changes in the kidney which, since they were first pointed out by Dr. Bright, have been chiefly studied in their connexion with *chronic* dropsy. That as rheumatic carditis may occur, and become latent as to its effects for some time, and yet implant the germs of future cardiac dropsy, so the stress or strain which befalls the kidney in cases of febrile anasarca, may set on foot a morbid process that long works silently and unobserved, but at last declares its operation by symptoms; the reproduction of the dropsy in a more chronic form being the most significant symptom of all. The acute attack may have been forgotten; there may have been no obvious (though there may have been ill-understood) indications of the renal affection; and its existence has been, therefore, unsuspected.

The discovery of intemperate habits would also be of importance in aid of our diagnosis, if these same habits had not a like influence in causing disease of other organs as well as of the kidney, and especially of the heart. There may, however, be no such episodes as these in the patient's history. The dropsy may have come on immediately after some exposure, or obviously injurious influence, yet not with acute symptoms, and in a temperate subject: in which case it is probable that the renal disease had pre-existed in a latent state. Or the anasarca may have stolen on by degrees, without any apparent cause.

But the most conclusive evidence of the renal disease is to be found in the conditions of the urine; which were fully explained to you in yesterday's lecture. I shall therefore only add four rules upon the subject, which have been laid down by Dr. Christison, and generally acquiesced in by Dr. Prout. These rules assert that organic disease, or granular degeneration, or granular disorganization of the kidney,—all which phrases we may condense into the compendious expression “Bright's kidney”—is present:

1. In most cases of febrile dropsy, including those which are consequent upon scarlet fever. To this proposition I have already given my full assent.

2. In all cases of anasarca, wherein the œdematous parts are elastic, and do not pit upon pressure. I am not so sure of this rule. I believe that the firmness of the œdematous parts has relation rather to the rapidity with which the effusion has taken place, than to the local origin of the dropsy. In proportion as the accumulation in the areolar tissue has been chronic and gradual, does the swelling receive and retain indentations from external pressure.

3. In most, or all cases of dropsy attended with diuresis, provided the urine be not saccharine. Such cases, Dr. Christison truly remarks, are far from being uncommon. Of course the diuresis here spoken of is such as occurs independently of diuretic remedies.

4. In all dropsies associated with urine of a very low specific gravity (say below 1010), and not exceeding the natural standard of quantity, whether it be albuminous or no. To the last two rules there are probably very few exceptions.

The dropsy which is dependent upon “Bright's disease” yields, not unfrequently, to treatment; but it is prone to recur. Of the renal disease itself the prognosis is, no doubt, very unpromising. Yet I do not think so despairingly of these cases as I once thought; and as many think. I have known a few instances of what seemed complete recovery after well-marked symptoms of the disorder. Certainly success enough has followed careful treatment, to encourage us to use all diligence in prosecuting such remedial measures as are already known, and in devising new ones. Of the two main forms of the disease, the large white kidney is the more immediately perilous. The appearance of oil in the urine is probably always of fatal omen.

I have been speaking of dropsies that are purely cardiac, and of dropsies that are purely renal. But I have already told you that disease of the heart and disease of the kidney frequently go together; and I have endeavoured to estimate their relation, in such cases, to each other. When both organs are structurally affected, the disposition to dropsical accumulation must evidently be augmented. What share they have, respectively, in producing the dropsy, it would be very difficult, and practically it is not very important, to determine.

In chronic general dropsy of a purely cardiac origin, the kidneys, being sound, offer the most convenient and eligible channel for carrying off the superfluous water. Diuretic medicines, therefore, rank among the most important of our curative expedients. When they fail to act, or prove insufficient for the purpose sought, we next have recourse, the state of the bowels permitting, to drastic or hydragogue purgatives.

Diuretics are notoriously of most uncertain operation; sometimes completely answering our wishes, oftener perhaps disappointing them altogether. Something may depend upon the way in which they are administered. There can be no doubt that liquids, after being conveyed into the stomach and intestines, pass thence into the blood by imbibition through the capillary vessels—nor any doubt that living membranes are subject equally with dead membranes to the physical laws of endosmose and exosmose. Hence it follows that remedies which are meant to reach the kidneys must be in a liquid form when taken, or must be capable of being dissolved afterwards in the fluids of the alimentary canal. In the last edition of his volume on

Urinary Deposits, Dr. Golding Bird lays down the further requisite condition, that the density of the solution must be considerably below that of the liquor sanguinis, or of the serum of the blood; lower, that is, than 1028. The proportion of solids (he says) dissolved in aqueous vehicles should always be less, when the purpose is diuresis, than 5 per cent.; otherwise that purpose is sure to be defeated: strong solutions of saline substances proving purgative through the exosmosis which they cause out of the blood—and weak solutions diuretic through the endosmosis which they cause into the blood. Dr. Headland, however, in his essay on the *Action of Medicines*—while he admits that a weak solution is more likely to pass off by the kidneys and a dense one by the bowels—questions, indeed I may say disproves, Dr. Bird's explanation of these facts. He shows that salines are in all cases absorbed into the blood, and that whether they are subsequently excreted through the kidneys or by the bowels, depends more upon the *quantity* administered than upon its degree of dilution. In fact the kidneys are not able to eliminate more than a certain amount of these saline medicines, which, to obtain the desired diuretic effect, should therefore be given in small doses, moderately diluted. The operation of diuretics is apt to be foiled when the bowels are irritable or lax. So likewise any impediment to the free entrance of liquids into the tributaries of the vena portæ from disease or congestion of the liver, which keeps those veins full—any mechanical hindrance to the subsequent course of the same liquids towards the emulgent arteries, from disease of the lungs or of the heart, producing general venous congestion—will tend to baffle the aim of drugs which are esteemed diuretic.

When the urine is strongly acid, and deposits, on cooling, a sediment like brick-dust, it may be well to try, at first, the alkaline diuretics, and particularly the salts of potass. Nitre added to the common saline draught; or a combination of the acetate and bicarbonate of potass; or the bitartrate in small doses; or the iodide of potassium; or the liquor potassæ. In my own experience the tincture of squills also has seemed to correct this superacid and turbid condition of the urine, while it increased its quantity.

The benzoate of ammonia is another salt which I have found to operate very powerfully, in several instances, as a diuretic.

Digitalis sometimes promotes, in a remarkable degree, the flow of urine; and this, in my judgment, is its most useful and manageable property. Small quantities of the tincture, or of the infusion, may be added to other formulæ. Or the powdered leaves may be combined in pills. But one of the best modes of exhibiting digitalis for this purpose is to give larger doses of the infusion, half an ounce, for example, in some cordial water, at intervals of four or six hours, till three doses have been taken in succession; and then to pause and note its effects; and to repeat the three doses, or not, accordingly.

The spirit of nitrous æther, and the compound spirits of juniper, and of horse-radish, have all of them well-marked diuretic properties, and may, with propriety, be added to most of the liquid formulæ for augmenting the discharge of urine. And, as vehicles for more active, or more concentrated ingredients, those vegetable infusions or decoctions should be chosen which are reputed to possess similar virtues; such as the decoction of broom-tops, or of juniper-berries, or of winter-green, or the infusion of buchu.

Squills, turpentine, the tincture of cantharides, are drugs of a more stimulant nature, more peculiarly adapted to cases in which there is no febrile disturbance, and the kidneys are obstinately inactive.

Sometimes a combination or farrago of diuretic substances proves more efficacious than larger doses of any of the ingredients administered singly: and the operation of some of these combinations is undoubtedly quickened and exalted, in many instances, by the addition of mercury. A fluid drachm of the official solution of the bichloride in each dose of a mixture; or small quantities of calomel, or of blue pill, when the medicines are given in a solid form. A very useful pill of this kind, much recommended by the late Dr. Baillie, consists of three or four grains of the pilula hydrargyri, mixed up with one grain of the dried powder of squills, and half a grain of the dried leaves of digitalis; to be given twice or thrice a day. Dr. Baillie states that squills and digitalis are much less effectual by themselves, than when combined with mer-

cury : which operates probably in relief of the portal circulation, by promoting a free secretion from the liver.

In choosing purgative drugs to aid the effect of diuretics in carrying off the dropsical fluid, or to take their place when these fail to act, we select those which produce copious and watery discharges from the bowels. A combination of jalap and cream of tartar has been long and deservedly esteemed for its excellent operation in this way. Gamboge is also a good cathartic. It may be given two or three times daily, in grain or two-grain doses, with a drachm of cream of tartar, suspended in two ounces of peppermint water. Or half an ounce of cream of tartar, mixed in six ounces of peppermint water, may be administered in one dose every morning. Croton oil, and elaterium, are still more powerful evacuants of serous liquid from the intestines. One or two drops of the former, or from a quarter of a grain to a grain of the latter, will be about a proper dose. It is astonishing how much relief to the feelings of the patient, and how great a diminution of the dropsical symptoms, are sometimes obtained by these active cathartics. Patients will earnestly beg for a repetition of them, even when their operation is attended, for the time, with considerable pain or sickness, and much general distress.

In addition to these measures for the removal of the collected water, attention must be paid to the actual condition of the heart. If the dropsy have been the result of anæmia, or of cachexy of the system, you must endeavour to strengthen your patient, and to repair his impoverished blood, by nutritious food and tonic medicine, and especially by the administration of steel. I told you formerly that preparations of iron have an exceedingly good effect, oftentimes, even in cases of *organic* disease of the heart, consisting in dilatation and tenuity, and consequently weakness, of its muscular parietes.

On the other hand, if there be violent palpitations of the heart, with a strong heaving impulse, you may appease the excessive action, and afford sensible comfort to the patient, by applying leeches, from time to time, to the præcordia.

Of the *renal* variety of chronic general dropsy, whether pure or mixed, the treatment is less accurately ascertained. The uncertainty which has perplexed men's minds respecting the nature of the renal disorder, has extended, in some measure, to their choice of remedies for it.

Whenever (in renal dropsy) acute symptoms and febrile disturbance occur, much relief may be expected from the abstraction of blood. When drawn from a vein, it usually shows the buffy coat. The existence at the same time of pain in the loins, would indicate the propriety of applying cupping glasses to that part. Nevertheless, the impoverishing effect of the disease itself upon the blood, and the probable dependence of some of the more distressful and alarming symptoms upon the thin serous condition of the circulating fluid, as well as the increased facility with which the dilute blood may transude outwards—these are circumstances which should induce every cautious practitioner to have recourse to this heroic remedy, only when it is clearly *demanded*. It is chiefly adapted to those cases in which the renal change occurs in connexion with acute or chronic inflammation.

One definite object, in the renal as well as in the cardiac variety, is to remove the dropsical fluid ; from which the danger and the suffering often chiefly proceed. But it is a more nice question, when the *kidney* is involved in the disease, how this is to be accomplished. Can we, with the same safety as in cardiac cases, employ diuretics ? It has been thought that we cannot. As the primary morbid state of the kidney is certainly often a state of active or inflammatory congestion, it has been feared that direct diuretics, such as are calculated to cause, keep up, or augment such congestion of the kidney, or to stimulate and irritate that organ, would be likely to accelerate the disorganizing process of which it is already the seat.

These views can scarcely now be considered theoretical. Their justness has been established, in respect at least to the nephritic kinds of renal dropsy, by those interesting results of modern inquiry which I yesterday brought under your notice. You had better, therefore, when you can, observe the caution which they suggest. You had better endeavour to empty the distended cavities, and to relieve the loaded areolar tissue, through the bowels, or through the skin. Sometimes, however,—more often indeed than in cardiac dropsy—we have the untoward complication of irritable bowels,

or habitual diarrhœa : and then drastic cathartics are inadmissible. But when this complication is not present, they are eminently useful.

Much benefit is sometimes derived from measures that act powerfully or steadily upon the cutaneous transpiration ; and especially from warm, or hot-air, baths. The hot-air bath is, in many respects, preferable to the common warm-water bath, and even to the vapour bath. Upon the principle of heterogeneous attraction, the escape of the liquid from the surface of the body is more promoted by a dry heat, than by water artificially raised to a high temperature, and even than by an atmosphere made moist, as well as hot, by vapour. The risk, moreover, of exposure to cold, and the inconvenience, and hazard of fatigue, are much less : for the hot air can be brought, with but little trouble or expense, to the patient as he lies in bed. I have often applied the *sudatorium* to patients labouring under renal dropsy, and they have obtained much relief from it : but the relief is seldom of itself sufficient, or of more than temporary duration. Still it is an expedient that should never be neglected ; and in pursuance of the same indication, diaphoretic medicines should at the same time be diligently exhibited. Dr. Osborne states that when the renal disease has been uncomplicated with other organic mischief, he has always found the dropsy to disappear upon the re-establishment of the functions of the skin.

These measures failing—as fail they often will ; and diarrhœa forbidding the use of drastic purgatives ; or drastic purgatives and diaphoretics together proving insufficient ; we *must*, even in renal dropsy, of whichever variety, choose the least of two evils ; or rather we must incur the risk of one possible and contingent evil, for the chance of obtaining what, if obtained, is a certain and positive benefit : we must endeavour to remove the dropsical accumulation by means of *diuretics*, whether these accelerate the progress of the disease in the kidney or not.

Such diuretics, therefore, are, in the first instance, to be selected, as seem the least likely to stimulate the kidneys injuriously. The bitartrate of potass has been found one of the most certain and useful. Digitalis also is esteemed safer, and therefore more proper for this purpose, than many others : and the simultaneous exhibition of these two has, perhaps, the surest effect of all.

When diuretic medicines act as we intend them to do, and increase the quantity of urine, they are commonly of great service by reducing the dropsical swelling. Sometimes, however, no impression is made upon the anasarca, although the discharge of urine becomes plentiful. This is a very discouraging prognostic circumstance. And the drugs that we employ are apt to be very capricious and disappointing. In some unhappy cases of renal dropsy, I have tried every known form and combination of diuretics, without augmenting the secretion from the kidneys. Probably their secreting power was destroyed or arrested by the physical disorganization of the secreting apparatus. Could we be sure of this, it would become our duty carefully to abstain from all such medicinal substances as the healthy kidney is prompt to excrete. Urea appears to be the main natural diuretic ; and in this disease it already exists in the blood in too great abundance. On the other hand, the watery ingredients of the blood are sometimes transmitted readily enough through the diseased gland. The advanced stages, or certain forms, of the malady are liable to be attended with diuresis. We may even suppose that the obstructed tubules may sometimes be washed out by the descending streams of aqueous liquid ; and Dr. Johnson's suggestion is worth your attention, that, in these circumstances, “and more especially, perhaps, in cases of chronic nephritis,” the safest and most useful diuretic is pure water.

It is yet an unsettled question whether mercury be advisable or even admissible, in these cases. The current of medical opinion sets against it : perhaps too strongly. It has been observed that salivation is apt to be produced by a small quantity of this drug ; and to be unusually troublesome and severe, without bringing any commensurate advantage. I mentioned to you formerly Dr. Farre's opinion, that mercury has the property of rapidly destroying red blood : if so, it must be regarded rather as an ally, than as an antagonist of this malady. On the other hand, some patients have appeared to recover altogether, after passing through a furious salivation. One of the reputed virtues of the mineral is that it promotes interstitial absorption—a property which the changes apparent in the kidney in some forms of renal dropsy would seem to render valuable.

When internal remedies prove ineffectual, and outward applications to procure

sweating miss their aim, we turn to those mechanical expedients which (in either variety of general dropsy) often afford ease, and prolong life, and may even, sometimes, perhaps, achieve a cure.

I have told you that the tense and stretched integuments occasionally give way; the areolar tissue sloughs, and from the breach thus made, water wells copiously forth, and great relief ensues. Sometimes, though very rarely, the whole of the accumulated liquid has so escaped, and the dropsy has not reappeared. The sore has healed, and the natural cure has been complete.

This spontaneous mode of draining away the liquid has been imitated by art. For the unwieldy legs become painful as well as cumbrous; the integuments threaten to inflame, or to mortify; and if we can diminish the tension by removing a portion of the included fluid, we avert or lessen this danger. The penis and scrotum also in the male, and the labia pudendi in the female, become, in many cases, enormously swollen, and hinder the exit of the urine, which is therefore spilled upon the tumid parts, rendering them erythematous and raw, to the grievous aggravation of the patient's sufferings.

Now seeing that vesications sometimes form upon the dropsical limbs, and give vent, in some degree, to the fluid, practitioners have been induced to follow that indication by exciting artificial blisters. But they are highly dangerous; leading often to gangrene of the surface thus inflamed. Within my recollection it was the custom to make sundry incisions with a lancet, in the œdematous legs. These gashes seldom healed again; but degenerated into sloughing sores; and not unfrequently they hastened the dissolution of the patient.

A vast improvement upon these expedients is the modern practice of acupuncture, which consists in perforating the integuments here and there with a fine needle.

It is surprising how much fluid may be let out in this way; and how much relief may be bestowed by this trifling operation. The liquid trickles rapidly forth; and I have known it soak through the patient's bed, and form a pool on the floor of the room. In one instance, a physician being my patient, the limpid fluid which thus oozed from a puncture in his thigh was caught, and collected in a glass, by means of a little gutter of oiled silk. It was found that ninety minims, or a fluid drachm and a half, escaped in a minute; which is at the rate of eleven ounces and a quarter in an hour: and this drain went on for upwards of four hours.

The surface on which punctures of this kind have been made sometimes becomes red: erysipelas supervenes, which it is difficult to arrest, and the patient sinks. In some of these cases the same event would probably have occurred, even although no punctures had been made, from mere tension of the integuments, and the progress of the disease. When such appearances present themselves, the affected limb should be kept in a horizontal position; and strips of linen, wetted with a solution of Goulard, should be applied to the inflamed surface.

Under the old system of incisions it was found (and reason would teach us to expect this) that there was more hazard of sloughing when they were made on the legs, than on the thighs. The risk is much less when needles are used. But even these punctures are not to be made without attending to certain precautions. They should not be too near each other: an inch and half, at least, should intervene between them. Neither should they be too numerous, nor too deep. The depth must depend upon the circumstances of the case; and especially upon the place where the puncture is to be made. The needle must not be pushed so deep as to penetrate or wound any fascia; for the danger of subsequent inflammation would thereby be increased.

Mead's plan, of making one incision, and no more, in either leg, on its inside, two fingers' breadth above the ankle, and through the areolar tissue, has been revived of late upon the continent, and commended here. The danger of sloughing is certainly less than when many cuts are made: and Dr. Todd points out, as advantages of this method, the rapidity with which the fluid escapes, and the avoiding "of that sloppy and soaking condition which inevitably ensues when the acupunctures are allowed to ooze all day."

The peritoneum may, at the same time, require to be emptied in the same mechanical way, by help of a trocar. I am always loath to recommend tapping, until the symptoms actually call for it, and until all other means of dispersing the water

have been tried in vain. But the circumstances that warrant or demand the performance of the operation, the dangers that attend it, and the means of obviating those dangers, were fully pointed out when we were on the subject of ascites.

By whatever means we may succeed in getting rid of the dropsy there will still remain (except in the comparatively few cases that are unconnected with organic disease, and depend simply upon debility and anæmia) the necessity for guarding against the re-accumulation of the water, by remedial measures addressed to the faulty organs. You may sometimes keep the disease of these organs in check, even when you cannot cure it.

In cardiac dropsies, besides the medicines already specified, undeviating temperance and regularity of life must be enjoined; and the patient should carefully, and always, avoid all active motion or exertion of the body, and all strong emotion of the mind; whatever, in short, might tend to hurry the circulation. You will scarcely be able to enforce this prudence, without plainly showing the patient the risk he will incur by its neglect.

In the renal variety of the disorder, in addition to the appropriate remedies already enumerated, particular attention must be paid to the avoidance of all exposure to cold and vicissitudes of the weather, and to keeping the surface of the body warm. Such patients should be constantly clothed in flannel from head to foot. To those who are able to choose their place of abode, I should strongly recommend resort to a warm climate. Some benefit may also be hoped for from counter-irritation—blisters or issues to the loins.

The diet in the chronic forms of the disease should be nutritive, but unstimulating. M. Solon suggests that if, in the renal cases, urea be detected in the blood, the patient should be restrained from too animalized a diet. Dr. Budd has had the same thought, and has put to the test, I believe, in the Hospital-ship Dreadnought, the utility of withholding all articles of food that contain azote. I have found this restriction entirely useless in one painful case, in which it was fairly enforced. In fact, the principle of such restriction appears to be wrong: the urea is furnished to the blood, not in the primary assimilative process, but in that which is secondary and destructive.

The discovery of the fatty character of one of these forms of renal degeneration has led to another plausible suggestion; viz., that the patient should be instructed rigidly to abstain from every kind of fat. But if the mottled and fatty kidney really be, as it probably is, one of the numerous issues of the scrofulous habit; this advice would seem to be of doubtful propriety, when we call to mind the confessed efficacy of some of the fixed oils, and especially of the cod's liver oil, in the treatment of strumous disorders. It is indeed the opinion of Dr. Williams, who bears strong testimony to this efficacy, that it results from the solvent power of the thin fish-oils upon the more concrete molecules of fat, by the morbid accumulation of which, the peculiar degeneration in question is constituted.

One more point, and I have done. Much unnecessary penance used to be inflicted upon dropsical persons, by stinting their allowance of drink. It was natural to suppose that the accumulation would increase in proportion to the quantity of liquid swallowed. But experience has shown this opinion to be erroneous, and

“crescit indulgens sibi dirus hydrops”

has ceased to be more than a poetical doctrine. The patient may safely be allowed to exercise his own discretion in this respect. When the peritoneum is full, distress is apt to ensue upon the distension of the stomach by drinks; but this source of suffering is soon discovered and avoided. The sick man is better able than his physician to judge which evil is the greater; the torment of unslaked thirst, or the discomfort that may be produced by its immoderate indulgence.

LECTURE LXXX.

Chylous Urine. Hæmaturia; its diagnosis, general and particular; Local disorders of the Urinary Organs on which it depends; Treatment. Disease of the suprarenal capsules; Bronzed Skin. Abdominal Tumours.

I HOPE I have convinced you that the morbid conditions of the urine are worth studying. You have heard, probably, of the quacks who call themselves "water-doctors," and who pretend that, by mere inspection of the urine of a patient living at a distance, they can tell what is the matter with him, and how he may be cured. This skill, which looks like conjuring, the scientific physician of the present day does really possess. Of some very important forms of constitutional disorder, and of some specific local maladies, he reads the sure evidence in the sensible and chemical qualities of the secretion from the kidneys. And I do not hesitate to say, that a rightly instructed person might form a more accurate opinion respecting a sick man fifty miles off, and prescribe for him more judiciously, upon being furnished with a vial of his urine, than some practitioners whom I have known could do, if they had the patient bodily before them. You may learn much (and so, no doubt, you ought) by prying into the arcana of the night-chair: but you may learn more, I am persuaded, by the habitual perusal of the chamber-pot.

I have not quite done with the subject.

Sometimes urine is voided, which appears to contain *chyle*. It looks white and milky, and stiffens as it cools into a tremulous jelly, like *blanc manger*, and takes the shape of the vessel into which it was passed. The coagulum gradually separates again into two portions: one of which is liquid and whitish, and when left at rest for a few hours throws up to the surface a sort of creamy matter, containing (as cream does) a butyraceous or oily principle; the other is a delicate fibrinous mass, of flesh-like appearance, having a red tinge from the presence of some of the colouring matter of the blood. This is the character of the urine passed a few hours after a full meal. When the patient has long been fasting, the urine is simply opalescent, and the coagulum small and partial. It never contains any casts of the urinary tubules.

Dr. Prout attributes this curious deviation from the natural qualities of the urine to a double fault; first, in the organs of assimilation; secondly, in the functions of the kidney. The chyle, from some derangement of the assimilative process, is not raised to the blood standard; and being unfit for its purpose, is ejected through the kidneys; and these organs, instead of converting it, as usual, into the lithate of ammonia, suffer it to pass through them unchanged.

Of this rare disorder I have not met with an instance. Dr. Prout had seen more or less of fourteen cases. Five of the patients were males, nine females. Two of the males, and one of the females, were below the age of puberty. Eight of the cases occurred in natives of the East or West Indies, or in persons who had lived for many years in hot climates. Mr. Thomas informs me, that during a residence of ten years in Barbadoes, he saw at least a dozen well-marked examples of chylous urine in negroes. It would seem, therefore, that a tropical climate predisposes certain individuals to this affection. In one case, drinking cold water while the body was warm seems to have been the exciting cause; and exposure to cold was thought to have had something to do with the attacks in other cases.

The general health suffers less than you might suppose. Two of the females, while labouring under the complaint, became pregnant, and brought forth healthy children; and one of the two lived nearly twenty years, with the disorder upon her all the time. Another of his female patients, who since his death has been seen by Dr. Bence Jones, first noticed that her urine was chylous in the year 1827. It continued so, with occasional intervals, till July, 1853, a period of twenty-six years, when the lady was (as she may be still) alive, and, this state of the urine excepted, in good health.

In the slighter cases there is usually some degree of feverishness, some uneasiness

in the back and loins, some thirst, a dry skin, and torpid bowels. When the malady is more severe, the symptoms approach to those of diabetes; the thirst is more urgent, the appetite unnaturally craving: and there is some degree of emaciation and debility. In this severer variety the urine is apt to coagulate before it leaves the bladder; and the patient experiences difficulty in passing it, the urethra being blocked up by the clots. Dr. Prout states that he has known this to constitute the most troublesome symptom of the disease. In one of the fatal cases the body was examined, and the kidneys found perfectly healthy. Occasionally the complaint ceases of its own accord, even for years, and then recurs without any apparent cause. We may conclude from these circumstances that it is a purely functional disorder.

With respect to treatment, little can be said. Dr. Prout has found several things of temporary service, in the chronic state of the affection. The mineral acids; astringents, such as alum, and the acetate of lead; opium; counter-irritation. But the suspended symptoms have always sooner or later returned. Dr. Bence Jones has put several drugs fairly to the test, and found the gallic acid more useful than anything else, though not a specific, in this disorder. In the case of a man, who also had formerly consulted Dr. Prout, the urine had been chylous, constantly, for more than a year. It ceased to be so two days after he began to take the gallic acid, and it remained free from the fatty admixture for 232 days, the acid having been continued for nearly two months. This looked like a cure. But the complaint recurred, and went, again and again. Twice subsequently the chylous condition ceased, after administration of the gallic acid, for the respective spaces of 237 and 242 days. The acid was frequently given to the large amount of two drachms daily, for weeks together.

Tannic acid was tried in this case: but it could not be taken in doses so large; and it caused much more nausea, and much more headache than the gallic acid. The chylous state was always abated by rest, and aggravated by exercise.

Urine which contains albumen exhibits it in the solid form under the tests of heat and nitric acid.

Yet I have met with one remarkable case in which those tests did not produce the usual precipitate, although an enormous quantity of an albuminous substance was passing out of the body in the urine.

This urine was of a high specific gravity. It became thick with heat, from a deposit of phosphates, but cleared again with a drop of acid. It gave no precipitate with an excess of nitric acid, unless left to stand, or unless heated and left to cool, when it became solid. This solid was redissolved by heat, and formed again as the liquid again cooled.

The case was one of *mollities ossium*. A full analysis of the urine has been published, in the *Philosophical Transactions* for the present year (1848) by Dr. Bence Jones, who found the peculiar substance thus secreted to be hydrated deutoxide of albumen.

There was as much of this albuminous substance in the urine, as there is of ordinary albumen in healthy blood. So far therefore as the albumen only was concerned, each ounce of urine passed was equivalent to an ounce of blood lost.

Dr. Bence Jones informs me that the same substance, in small quantity, is contained in pus: and has received the name of *pyine*. He thinks it probable that the substance which characterizes chylous urine, is closely related to this.

Lastly, the urine may contain *blood* itself: and I proceed to consider some of the phenomena that occur in connexion with *hæmaturia*; under which term I would comprehend every kind of bleeding from the urinary organs.

Blood alters, of course, the colour of urine with which it is mixed: giving it, in some instances, a bright red tinge, and causing it, in others, to assume a dark hue; to become brown, like coffee, or even to approach to blackness. Hence we are sometimes too ready to conclude that urine of a distinctly red colour, or so very dark as to appear almost black, derives its peculiar tint from blood that has somehow mingled with it.

But, in truth, urine may be perfectly red, or nearly black, and yet be quite free from blood. There are certain substances which, when taken as food, invariably

impart a red colour to the urine. One of these is the prickly pear, or Indian fig as it is sometimes called, the *cactus opuntia* of botanists. When the Spaniards first took possession of America, many of them were alarmed by observing that they passed what they supposed to be bloody urine; but it was soon discovered that the red colour of the secretion was owing to the liberal use they made of that fruit. Dr. Hennen, in his book on *Military Surgery*, quotes a precisely similar example from Elliot's Journal of his Travels for determining the boundary of the United States. He says that his "people ate very plentifully of this substance at an island of the Mississippi (Kayo-ani), and were not a little surprised the next morning at finding their urine appear as if it had been highly tinged with cochineal. No inconvenience resulted from it. It would seem (he continues) that the juice of this plant may be analyzed into a crimson dye by other processes beside that of the cochineal insect."

Another vegetable substance with which, in this country, we are more familiar, and which will produce the same effect, is *beet-root*. Desault relates the case of a person who noticed that he every morning voided urine of a deep red colour; exactly such as would result from adding fresh blood to that liquid, except that no deposit took place. The man became frightened at this, and consulted M. Roux, who, after some examination, began to suspect that the water owed its red appearance to some other cause than an admixture of blood. It turned out that his patient was in the habit of supping every night upon the red beet-root; and as soon as, by M. Roux's advice, he relinquished this article of diet, he was freed at once from his supposed bloody urine, and from his fears.

A similar tinge is said to be given to the urine by the use of *madder* as food, by some species of strawberries, and by drinks made of sorrel. *Logwood*, which we sometimes use in medicine, has the same effect. *Rhubarb* also, and *senna*, give to the urine, *if it chance to be alkaline*, a blood-red colour.

It is right that you should know these facts: for by swallowing large quantities of such substances, and by complaining of sensations which they do not really feel, impostors may endeavour, without any difficulty, or pain, or danger to themselves, to deceive others into a belief that they are suffering under some serious and disqualifying disease, and are proper objects of charity. Moreover, a knowledge of the effects of these vegetable matters may sometimes enable you, as in the case mentioned by Desault, to remove unfounded anxiety and alarm from the minds of persons who are innocently and unconsciously giving themselves red urine.

The natural tint of the urine inclines towards redness, independently of any admixture of blood, in many instances of fever, and of acute inflammation. Occasionally urine of a pink colour is passed by persons who are subject to obstinate dyspepsia connected with organic disease. This pink tint is most apparent when the water is contained in an opaque, shallow, white vessel.

Again, urine of so deep a colour as to be called, in common parlance, *black*, may or may not owe that hue to the presence of blood. When blood is the cause of the unnatural colour, the blackness must be ascribed to the chemical action of some free acid upon the blood: as I showed you formerly to be the case with blood that is vomited, in hæmatemesis.

I also pointed out to you some little while since, that the urine, in jaundice, sometimes *seems* to be black, when it is collected in large quantity, and in a deep vessel. This colour is merely a concentration of yellowness, as appears at once upon diluting the urine with water. It then assumes a bright yellow colour. The aspect of the skin in icterus will always secure you against mistaking or overlooking this cause of black urine.

There has been observed, also, though very rarely, a form of black urine, depending upon the presence in that secretion of a peculiar principle to which Dr. Marcet gave the name of melanin acid. The only specimen of really black urine that I ever saw, was shown to me by Dr. Prout; who knew nothing, however, of the circumstances under which it was voided. It appeared to me to be full of coal-dust.

With these two exceptions, almost all urine that is of a very dark or blackish colour owes that quality to the circumstance of its containing blood, which has been more or less altered, by various causes, from its original appearance.

When blood is present in any considerable quantity, a portion of it subsides to the bottom of the vessel, and may be recognized without any difficulty. And even when

there is not enough blood to give a marked and characteristic deposit, a very small admixture of it will be found to disturb the natural transparency of the urine, rendering it of a smoke-brown, or dull cherry colour: whereas the reddish or pink urine which contains no blood is clear and untroubled; and if, on cooling, it throw down a sediment, that sediment may be redissolved by heating the urine—a result which does not take place when a portion of blood has been deposited. Another rough test is, that a mixture of urine and blood tinges a piece of white linen dipped into it, of a red colour. A better criterion is afforded by gradually raising the suspected urine to the boiling temperature. If it contain blood, a greyish brown flocculent precipitate, consisting of coagulated albumen tinged with the colouring matter of the blood, will form, and gradually subside, and leave the supernatant liquid clear, and with its natural tint. But if you use the microscope, that will furnish you with the best evidence upon this point. If there be blood in the urine, there will be blood-corpuscles, turgid or collapsed, diffused through the urine, or collected at the bottom of the vessel: and whatever modifications they may present, they may always, Dr. Bird says, be identified by “their non-granular surface, uniform size, and yellow colour under the microscope.”

We have by no means accomplished the diagnosis when we have merely ascertained that there is blood in the urine; and that the case is a case of hæmaturia. The question remains, of what is such hæmaturia a sign? The blood emerges from the urethra, but it may have been poured out at any point of a long and somewhat complex tract of mucous membrane. It may have proceeded from one or both of the kidneys, from each or either ureter; from the bladder; from the prostate gland; or from the urethra.

Hæmaturia strictly idiopathic must be very rare. Cullen remarks that neither he nor any of his friends had ever met with an instance of it. I shall mention presently the only example of hæmorrhage from the urinary organs, apparently idiopathic, that has fallen under my own notice.

Blood in small quantities is excreted with the urine in that acute affection of the kidney which I have already spoken of as lying at the root of most, if not of all cases of febrile dropsy. Respecting its origin in such cases we need have no doubt: for besides the colouring matter and corpuscles of the blood, the urine is found to contain blood-casts, which have obviously been moulded in the urinary tubules, and in which epithelial cells, detached from those tubules, are often entangled. The same phenomena present themselves sometimes—though much more rarely—in the chronic forms of Bright's disease. Blood-casts, without epithelial cells, have been seen by Dr. Johnson in a case of strangury produced by oil of turpentine; and it is probable that the appearance and conditions of the urine are the same in strangury from cantharides. Hæmaturia is occasionally, I believe, vicarious of some other hæmorrhage, and especially of bleeding from the hæmorrhoidal vessels: so that it is always right, in obscure cases, to inquire whether the patient has been habitually subject to hæmorrhage from the rectum; and if so, whether that hæmorrhage is suspended. These cases have even been called *hæmorrhoides vesicæ*.

Hæmaturia occurs also, independently of any strictly local complaint, in the course of certain disorders which affect the system at large; especially in scurvy and purpura hæmorrhagica. Bloody urine is sometimes a symptom, and one of the most fatal agury, in typhus fever, small-pox, measles, and the plague.

But setting aside these more general forms of hæmaturia, let us inquire what local affections of the urinary organs, besides those already referred to, may give rise to hæmorrhage; and how, under different circumstances, we are to interpret this symptom.

One very common source of hæmorrhage from the urinary passages, is the presence within them of calculous matter. The pressure occasioned by the aggregation of the earthy mass, when it is formed in the kidney, or by its accidental change of position, lacerates, or lays open by ulceration, some of the smaller vessels with which it is in contact. And in those cases in which a calculus descends into the bladder, and is ultimately voided, it may, in succession, give rise to hæmorrhage, first from the kidney from which it is separated; secondly, from the narrow tube of the ureter through which it is forced; thirdly, from the bladder which it enters, and wounds,

or irritates; and fourthly, from the urethra in the last stage of its progress out of the body.

There will be the same liability to hæmaturia, if the concretion, instead of coming down from the kidney, be formed originally in the bladder. The appearance of blood in the urine suggests therefore, in many cases, the fearful suspicion, that there is, or is likely to be, a stone in the bladder. Dr. Heberden, in his *Commentaries*, says, "urine made of a deep coffee colour, or manifestly mixed with a large quantity of blood, has within my experience been very rarely the effect of any thing but a stone in the urinary passages. I therefore suppose a strong probability of this cause, whenever I see this appearance."

Again, blood may proceed from the kidney, or from the bladder, in consequence of malignant fungous growths, to which those parts are liable: a disease which, though more surely fatal than the stone, is scarcely, to the unhappy subject of it, so appalling.

Hæmorrhage may take place from the surface of the bladder from chronic disease, not cancerous, of that membrane. Mr. Howship has recorded an instance of this kind which occurred in Mr. Heaviside's practice. An old East Indian, who had long been subject to nephritic complaints, was suddenly seized with what was thought to be retention of urine. A catheter was passed, but as no water flowed it was supposed that it had not entered the bladder, in the situation of which there was a manifest tumour. The patient died the next day; and the bladder was found distended by a very large coagulum of blood which had come from the diseased mucous membrane. There was no trace of hæmorrhage in the kidneys, nor in the ureters.

I hold in my hand a preparation showing disease of the prostate gland, which had been accompanied by hæmaturia.

Now we judge of the exact seat of the hæmorrhage, and of its cause, partly by the nature and appearance of the effused blood, and partly by the symptoms that precede or accompany the bleeding.

Dr. Prout states that "when blood is derived from the *kidney*, it is in general equally diffused throughout the whole urine: on the contrary, when derived from the bladder, the blood for the most part comes away in greater or less quantity at the termination of the discharge, the urine having previously flowed off nearly pure."

There are also certain modifications of the sensible qualities of the excreted blood, by means of which the same eminent physician thought he could pronounce, with considerable confidence, that the hæmorrhage was owing to malignant disease. "The red particles of the blood (he says), discharged in the earlier stages of fungoid disease, have often a remarkable appearance, and *appear to the eye* larger than natural; so that after they have subsided to the bottom of the urine, they at first sight somewhat resemble grains of lithic acid gravel, and, like that substance, when the vessel is inclined, may be distinctly seen to roll along the bottom. From this peculiar appearance of the red particles of the blood, the presence of malignant disease may be often suspected before the symptoms assume a decided character." In a more advanced stage of the disease, there is often a dark-coloured offensive bloody sanies in the urine, and more or less of mechanical impediment in passing it. I should conceive that the microscope might aid the diagnosis of such cases.

There is one phenomenon which, whenever it occurs, is very characteristic of hæmorrhage from the kidney, or from the commencement of the ureter. I mean the expulsion, with the urine, of slender cylindrical pieces of fibrin, which have evidently been moulded in the ureter, and subsequently washed down into the bladder by the descending urine. These little coagula are commonly of a whitish colour, the red particles of the blood having been removed; and they look like slim maggots, or small worms. They denote, with much certainty, that the hæmorrhage which they accompany is renal.

Such, then, are some of the points of diagnosis furnished by the qualities of the excreted fluid itself.

The bleeding may be presumed to come from the kidney, or from the upper part of the ureter, when it is accompanied or preceded by a sensation of heat, or of weight, or by some degree of pain, in the situation of the kidney; especially if these uneasy feelings are confined to one side of the body. This presumption will of course be strengthened if calculi have been known to descend from the kidney; and converted

into certainty if the patient suffer, together with the hæmaturia, a fit of the gravel; and if there be no symptom of stone, or of disease, in the bladder. As the blood comes, in these cases, from the calices or the pelvis of the kidney, the urine contains no blood-moulds of the renal tubes.

On the other hand, when no symptoms referable to the kidney or to the ureter are present, while there are signs of stone, or of disease of the bladder, or of a diseased prostate — a mixture of mucus with blood; occasional retention, or a sudden stop in the stream, of urine; pain referred to the glans penis immediately after the bladder is emptied—then we conclude that the blood proceeds originally from that receptacle.

When pure blood comes away, either *guttatim*, or in a stream, unmixed with urine, and neither preceded nor accompanied by any desire to make water, it is probable that the *urethra* is the locus of the hæmorrhage.

Bleeding from the surface of the urethra doubtless may, and commonly does, proceed from some mechanical injury done to that channel: as in the passage outwards of a fragment of stone, or inwards of a surgical instrument. But it is probable that blood may sometimes exude in considerable quantity from ruptured capillaries of the same membrane, under circumstances which favour or produce a strong determination of blood to the genital organs. A young man came to the Middlesex Hospital with hæmorrhage from the urethra, and said that he had lost a considerable quantity of blood in this way, within a few hours. The hæmorrhage appeared to have been the consequence of excessive indulgence in sexual intercourse. His own account of the matter was that he had passed the night with a female, in whom the monthly period had just returned; and he ignorantly fancied that the hæmorrhage from his own person was the result of a sort of contagion. However, the bleeding was permanently arrested by the introduction of a bougie, which was allowed to remain for a short time in the urethra. This was the solitary instance to which I alluded just now, of (perhaps) idiopathic hæmorrhage, occurring within my own knowledge. When the hæmorrhage comes originally from the urethra, the blood may regurgitate into the bladder, and coagulate there; and mislead an observer into the belief that the hæmorrhage was vesical.

It appears then, that, in many instances, certain local symptoms are associated with hæmaturia, and point distinctly to the part of the urinary apparatus whence the blood proceeds.

But many cases are very obscure. Blood sometimes appears, mixed in greater or less quantity with the urine, when there is no pain, nor any other sign which would lead us to fix upon one part rather than another as the source of the hæmorrhage. Now I believe that hæmaturia, bearing this indeterminate character, will generally turn out to be *renal*, and to depend upon concretions in the kidney. This conclusion will be strengthened if (as often happens) there are more or fewer *pus* globules excreted with the blood. It is true that the hæmorrhage which results from cancerous disorganization, whether of the kidneys or of the bladder, may also be painless. But cancerous disease of these organs (unless it extends from parts in the neighbourhood, as from the rectum, or from the uterus, to the bladder) is very rare; and when it does occur, the nature of the case may usually be ascertained from those peculiar qualities of the effused blood which I have mentioned as being characteristic of malignant growths.

A calculus can seldom remain long in the *bladder*, at any rate will seldom cause bloody urine, without giving some other notice of its presence there: but concretions form in the kidney, sometimes in great numbers, and reach a considerable size, and remain there long, without furnishing any signal from which we might suspect their existence; except (perhaps) the occurrence of hæmaturia. We know this, because calculi are frequently met with in the kidneys of persons who have never suffered any pain or obvious derangement of the urinary organs during life; and because, in other persons, in whom such calculi pass down from the kidney towards the bladder, the first notice of their existence is often given by the acute suffering they inflict during their transit through the narrow ureter.

Yet though calculi may lodge in the infundibula, or in the pelvis, of the kidney, without manifesting their presence by exciting pain, it is very conceivable that, by progressive enlargement they may lay open, or, by accidental change of position they may wound, some of the smaller blood-vessels of the part, and so give rise to painless

hæmaturia. It will strengthen the presumption that such is the source of the bleeding, if it have succeeded (as hæmorrhage from the urinary passages often does succeed) to a fall; a shock, or jar of the body; or jolting on horseback, or in a carriage. Similar movements may occasion bloody urine when there is stone in the bladder; but then the irritation will be *felt* in that sensible part; the hæmaturia will *not* be painless; the bleeding will not be the only symptom.

It is then, I say, my belief that very many of the obscure cases of hæmaturia may be referred to renal calculi: and if this view of the subject be correct, it will render it probable that the alleged instances of idiopathic hæmorrhage from the kidneys ought thereby to be reduced in number.

The expulsion of the blood in hæmaturia, whether it be painful or not, is sometimes attended with severe rigors. I mentioned before that, in some persons, almost any irritation of the urethra, the passing of a bougie for example, will bring on a shivering fit. I had some time ago a patient under my care in the hospital, who had hæmaturia of an obscure kind, and the discharge of blood was always marked by a smart rigor. Dr. Prout speaks of an instance of obstinate hæmaturia in which a shaking fit constantly preceded the hæmorrhage. Dr. Elliotson, too, in one of his lectures, gives an account of a case of intermittent hæmaturia. The patient was under his care in St. Thomas's Hospital, and had formerly had the Walcheren fever. He was admitted for ague, and every time that the cold stage of his attack came on, he voided a quantity of pure blood from the urethra. He was cured, by quina, both of his ague, and of his hæmorrhage.

If we may trust to the records of physie, instances of periodic hæmaturia are not uncommon.

One circumstance yet remains, worth noticing, in respect to hæmaturia; and it depends upon the hæmorrhage itself rather than upon the disease of which the bleeding is a sign. I allude to the coagulation of the effused blood in the bladder, however it may have got there. This circumstance is sometimes the source of much inconvenience, and suffering, and even of danger, to the patient. It may cause retention of urine, and all its evil consequences; and a still worse event is, that the coagulum sometimes supplies a nucleus, around which calculous matter is deposited, and thus lays the foundation of that horrible malady, "the stone."

You will perceive, from what I have said, that the *treatment* of hæmaturia resolves itself, in most cases, into the treatment of the disorder, or bodily condition, with which the hæmorrhage is associated, and of which it is merely a symptom.

Sometimes, however, the bleeding itself is so profuse, or so long-continued, as to require direct efforts on our part towards its restraint.

"When (says Dr. Prout) the bladder becomes distended with blood, and complete retention of urine in consequence takes place, recourse must be had to a large-eyed catheter, and an exhausting syringe, by the aid of which, and the occasional injection of cold water, the coagula may be broken down and removed. If the hæmorrhage be so profuse that the bladder becomes again distended with blood in a very short time, the injection of cold water into the rectum or bladder is sometimes of great use; and should these means fail, from twenty to forty grains of alum may be dissolved in each pint of water injected into the bladder; a remedy that seldom fails to check the bleeding, even when the cause is malignant disease. I have never known any unpleasant consequences follow the use of this expedient, and have seen it immediately arrest the most formidable hæmorrhage, when all other means had failed; and when the bladder had repeatedly become distended with blood, almost immediately after its removal."

Among remedies given by the mouth, the same physician thought highly of the acetate of lead. I have mentioned before, in these lectures, a nostrum called, after the name of its inventor, *Ruspini's styptic*. This has often been known to put a stop to hæmorrhage which had resisted other remedies. I will read you one example of this from Sir Benjamin Brodie's published lectures. Speaking of hæmaturia, dependent upon disease of the prostate gland, he says: "Those medicines which operate as styptics when taken internally, and which are useful in cases of hæmorrhage from the lungs, are also useful in hæmorrhage from the prostate. I had a patient with very diseased prostate. A frightful hæmorrhage took place. The usual methods of treatment were adopted, but were of no avail. The skin became pale, the pulse

became weak, and the patient was exhausted; yet the bleeding continued. Large quantities of blood were drawn off with the catheter: nevertheless the bladder continued to become more and more distended with blood, and was felt prominent in the belly as high as the navel. All other remedies having failed, I gave the patient a dose of the nostrum known by the name of Ruspini's styptic, and repeated the dose two or three times in the course of the next twelve hours. In about half-an-hour after the first dose was taken the hæmorrhage ceased; and it never returned. The patient lived a year and a half afterwards, and there was no reason to believe that any ultimate harm arose from the bleeding."

For a long while this nostrum seems to have baffled analysis. The late Dr. Maton told me that Dr. Wollaston had examined it, and had arrived at the negative conclusion, that it contained no metallic substance. D. A. T. Thomson afterwards announced that it mainly consists of a solution of *gallic acid* in alcohol, diluted with rose-water.

There is no substance more highly spoken of as a remedy for internal hæmorrhages by foreigners, and especially by the French, than the extract of *Rhatany* root, the *Krameria* of our Pharmacopœia. A woman was sent to me by my colleague, Mr. Arnott, complaining that for some weeks she had been passing bloody urine. She had gone through the ordinary routine of treatment without benefit. There were no symptoms present which threw any light on the precise source or cause of the hæmorrhage. I recommended a trial of the rhatany, and she began to take a scruple of the extract, mixed with water, three times a day. As in Sir Benjamin Brodie's case, the hæmaturia ceased after the first dose, and it did not return for many months. I mention this instance the rather, because the *gallic acid* enters into the composition of this vegetable extract also.

Now the gallic acid is one of those substances which, when introduced from the digestive organs into the blood, passes through the round of the circulation unchanged, and reappears in the urine. We may conceive, therefore, that it stays internal hæmorrhage by exerting its astringent property upon the ultimate capillary blood-vessels in its passage through them. It certainly is applied, in solution, after its elimination from the blood, to the urinary passages: and thus, in hæmaturia, it may be presumed to produce its styptic effect upon the bleeding surface.

To the same principle are owing, I believe, the astringent and styptic virtues of uva ursi, bistort, tormentil, the pomegranate, kino, catechu, and the several preparations of gall nuts. But as the efficacy of the gallic acid in restraining internal hæmorrhage is now well established, I would recommend you to employ it in its separate and simple state; since it may thus be prescribed in quantities more definite and precise, than would be possible in its natural combinations with so many different vegetable matters. It may be given three or four times a day, in doses of five or ten grains each, suspended in water by means of mucilage.

In cases of vesical hæmorrhage, with an alkaline state of the urine, much benefit has been obtained from a steady use of the muriated tincture of iron.

In former courses of these lectures I have said nothing—for I knew nothing—of the morbid conditions of the *supra-renal capsules*. I was ignorant alike of their physiology and of their pathology; of their uses and of their diseases. A pathology, however, they have, which vindicates the importance of these little organs in the bodily economy, although it does not disclose their purpose. The suspension of their function (the necessary result of the destruction, or the extensive impairment of their structure) is fatal to life: and this mortal inward change is revealed before death by one very conspicuous signal—unregarded, indeed, till our own day, and reserved for the sagacity of our distinguished countryman, Dr. Addison, to discern and to interpret. It is very remarkable that two physicians living at the same time, in the same town, and attached to the same hospital, should have brought to light two most serious forms of disease, utterly unknown before, in parts of the body so contiguous: and have thereby won for themselves an enduring place in the records of medical science. Henceforward the names of Bright and of Addison must be held in honourable remembrance whenever mention is made of renal and of supra-renal pathology.

Without dwelling upon the steps which led Dr. Addison onwards to his remarkable discovery, I will describe the group and succession of symptoms that ordinarily result from the spoiling of these internal organs.

It is not uncommon to meet with a sick person whose history is of this kind. He knows not how, nor precisely when, his illness commenced, but he has gradually fallen from his usual state of health : has become weak, pale, thinner, but generally not emaciated, languid, spiritless, unequal to bodily or to mental exertion, with flabby muscles, and a soft pulse, which commonly is very feeble also.

For this deteriorated and anæmic condition you can trace no intelligible cause. There has been no exhausting profluvium ; no loss of blood, morbid or artificial ; no diarrhoea, diuresis, or other drain upon the strength ; no wasting excess or indulgence ; no mental shock or anxiety. No fault is discoverable in the lungs, in the heart, in the kidneys, in the digestive organs ; no direct evidence of malignant disease in any part. Yet the diminution of strength is progressive — faintness and vomiting sometimes supervene — the mind becomes confused, the pulse grows weaker and weaker, until at length the flickering lamp of life goes out, or is extinguished in a sudden convulsion.

This unexplained train of symptoms should suggest the suspicion of disease in the supra-renal capsules ; and the suspicion will be turned into something like certainty, if, during the progress of the case, a change of colour begin to be perceptible in the patient's skin, first and chiefly in parts that are uncovered by the dress, as the face and hands, but elsewhere also. The colour which thus takes the place of the natural hue, is a brownish yellow. You fancy, while it is yet slight, that the hands and face may have been tanned by the sun : or that the patient may be labouring under a dirty-coloured jaundice. This latter notion is, however, at once refuted by the pearly whiteness of the conjunctiva, the paleness of the finger-nails, and the absence of any bile-tinge in the urine. Dr. Addison speaks of this colour, which deepens with the advance of the disorder, as being dingy, smoky, as presenting various tints or shades of amber, or of a chestnut brown. It is somewhat like the stain produced by the juice of walnuts, or by the tincture of iodine ; or, finally, the skin looks, in the affected parts, as though it had been *bronzed*. And the name of *bronzed skin*, familiarly given to the complaint, is preferable, while we are still so ignorant of its real nature, to any more formal appellation which might be derived from the Greek or Latin.

This hue is often partial, and occupies principally the front of the body and of the limbs, especially of the thigh. When it is spread over the whole surface, it varies in intensity, being darkest in the flexures of the body, in the armpits, and groins, round the navel, and upon the scrotum. Sometimes it is deeper here and there, and gives a mottled appearance to the surface ; and sometimes it is diversified with white patches, in which the skin is blanched, is more white and colourless than healthy skin, like the nails and the conjunctivæ ; and the hair on the head and on the pubes, corresponding to these spots, becomes perfectly white.

In several instances the blood, when examined under the microscope, has been found to contain an unusual number of white corpuscles.

The body and breath of the patient have exhaled, in two or three recorded cases, a peculiarly offensive and penetrating smell. In one report this odour is spoken of as being somewhat like that of a negro.

Though the disease is mostly a fatal disease, the state of the renal capsules is not always the same. Sometimes they are seen to be cancerous, sometimes enlarged, sometimes dwindled and atrophied. Most frequently of all they have undergone a calcareous degeneration, or have been converted into a softer putty-like substance. It is not, apparently, upon the character of the change, so much as upon its extent and completeness, upon the utter destruction of the natural texture of the capsules, and the consequent abolition of their functions, that the occurrence and march of the specific symptoms depend. The rapidity of the morbid change may also modify the outward manifestations of the disorder.

Disease of the supra-renal capsules has, in a few examples, been met with when there had been none of the characteristic bronzing. This is believed to have occurred only when the alteration of structure was *partial* or *recent*. One of them may be affected, the other sound ; or each, being unsound, may yet retain enough of its proper structure to enable it to fulfil its office, whatever that may be. Again though both capsules may be pervaded throughout by the same morbid process, there may not

have been time for the production of the peculiar colour of the skin, which is not one of the earliest symptoms, and which augments as the malady makes progress.

That profound disorganization of the supra-renal bodies, and bronzing of the surface, stand to each other in the relation of cause and effect, is rendered the more probable by the negative evidence which has been collected on this subject. In 500 inspections of the dead body conducted by Drs. Wilks and Habershon, in all of which the renal capsules were examined, disease of those organs was never found without its having been predicted during life, except in two instances. In one of these the skin *had* shown a slight dinginess, and a large mass of cancerous disease involved the whole of *one* of the capsules. In the other case also, one only of the capsules was affected; a few malignant tubercles grew from its surface.

Once only, so far as I know, has this peculiar bronzing of the skin been observed, with a perfectly healthy condition of the supra-renal capsules. The capsules themselves, and portions of the altered skin were shown by Mr. Hutchinson at a recent meeting (March 17, 1857) of the Pathological Society of London. This occasional dissociation of the two phenomena does not disprove the law which in so many more instances connects them as cause and consequence: it only shows that the bronze-like skin may be due to some other cause than disease of the capsules. You will do well to guard yourselves against mistaking some forms of *pityriasis* for this bronzing disorder. Pityriasis is a vegetable parasite of the human skin; and its vegetable character may be readily detected by the microscope.

I have said that the disease is *mostly* fatal, by which I meant that perhaps it is not invariably so. In not more, however, than in one or two recorded instances, has the characteristic colour disappeared, with the rest of the symptoms, and health been restored. Our knowledge of the subject is yet very crude and imperfect: but, admitting the correctness of the diagnosis, it has been reasonably conjectured that in these cases the whole of both capsules might have suffered some remedial change—some congestion or moderate inflammation for example—which at length receded and ceased, without ultimate damage to the integrity of the parts affected.

Again, to meet the opposite difficulty, of general disease of the capsules unattended by bronzed skin, it has been supposed, as I just now stated, that the whole of each capsule may undergo rapid softening and disorganization, under *acute* inflammation or some other spoiling process, and so the disorder prove fatal, before there has been time enough for the skin to assume the tawny hue.

What the functions of these little bodies may be, Physiology has not yet pronounced. They are amply supplied with blood; they have a cortical and a medullary structure analogous somewhat to those of the nervous centres; and they have direct and numerous relations with the great solar plexus. That they are concerned in the preparation and maintenance of the blood: that they influence the functions of the sympathetic system of nerves: that they regulate the formation, or the destruction, or the distribution of the animal pigments: these are among the guesses at their purpose. In support of this last guess is the fact that the colouring matters of the body are, to a certain extent, misplaced. The dark bronze-like hue, which more than one observer has described as giving to the patient the complexion of a mulatto, has been ascertained to be produced by dark granules, or cells, in the rete mucosum. Indeed the aspect of the rete mucosum, as seen under a microscope, approaches closely to that of the negro. It is said that the renal capsules are very large in the negro, and very small in the white or albino rabbit. How this may be I cannot say, but it would seem that according to this view of the disorder, these conditions should be just exactly reversed. Certainly, in the disease, the less there is of efficient renal capsule, the more there is of the dark pigment beneath the skin. In one of Dr. Addison's published cases, black spots were sprinkled over many of the abdominal viscera.

My own experience of this formidable disease has been but small. The barrister whose case (the 6th in the book) is described by Dr. Addison, was a patient of mine; and it was a vast comfort to me to have his advice and help under circumstances so distressing.

In January, 1856, I was consulted at my own house by a surgeon from the country, thirty-four years old, who was evidently drooping under the same malady. His face had a tanned appearance, his hands were bronzy, with pink contrasting finger-nails, his scrotum was very dark, and a few soot-like spots were scattered here and

there upon his skin. His urine was light coloured. His stools had never wanted bile. There was no tinge of yellow in his eyes.

He told me that he first noticed the dark colour of his scrotum in 1853. He died in April, 1857. The disorder existed therefore for four years at least. He began to perceive that he was unwell — to feel weak, to waste, to suffer fits of languor and depression, and to change in complexion — in December, 1854. Cold weather always distressed him.

The course of this gentleman's disease was marked by fluctuations. He regained flesh and strength at Hastings, the bronze-like hue varied in depth, his spirits were less depressed, and he resumed very active duties, as a coroner, and in his calling as a surgeon; but he sank at last under some acute affection of his larynx.

The supra-renal capsules were found large, and infiltrated with crude and suppurating tubercular matter. In the year 1847 Mr. S. was near dying from an abscess in the loin. From the cicatrix of this abscess a closed sinus was distinctly traced to the right capsule.

This case was remarkable for its duration, and for the energy which the patient displayed even in a late stage of the disease, and between occasional periods of most distressing prostration, palpitation, and sickness. During his last fatal attack it was noticed that a very foetid smell proceeded from his body.

Castig my memory backwards, I cannot but suspect that similar instances, transiently seen among my home patients, may heretofore have been erroneously set down as obscure cases of jaundice.

It would be idle to speak to you of any *cure* for this disorder. A strengthening plan, both of diet and of drugs, would naturally suggest itself. Mr. S. believed that he improved greatly for a time under quinine, and Margate ale. The pallor and the feebleness invite to the use of steel: but the malady which has, perhaps, occasionally yielded to time, and to the restorative force of nature, has been obedient to no special effort of our art that I am aware of.

I am unwilling to take leave of the cavity of the abdomen, without saying a few words (very few they must be) respecting the various kinds of *tumours* to which it is obnoxious. It may seem strange that the diagnosis of abdominal tumours, which manifest themselves to the touch and to the sight, should be so difficult and puzzling as it often is. I mentioned some reasons for this before: the loose and shifting manner in which some of the viscera of the belly are packed and fastened; their liability to enlarge beyond their natural limits; their accidental dislocations under disease. It would be vain to attempt even a sketch of the infinite variety of these deviations from the healthy state. Every case of abdominal tumour forms a separate object of study, and must be judged of by its proper circumstances. All that I can profess to do, is to offer you some rough hints on this interesting subject.

Some kinds of tumour result from morbid growths; such are all the varieties of cancer: some from the presence and multiplication of parasites; of which we have examples in collections of hydatids: some are produced by the distension of hollow organs; as when concretions, or faecal matters, or gases, lodge in the intestines; or when urine accumulates and is pent up in the bladder: some consist in the mere enlargement of parts.

Let us enumerate the principal of these; that you may know what chiefly to expect.

1. There are, I say, tumours from lodgments in the *bowels*; and these are more hopeful than most kinds of abdominal tumours. Sometimes the stomach, or some part of the intestinal canal, is distended in consequence of a mechanical impediment to the course of its contents: and this impediment may be invincible.

2. *Ovarian* tumours are very common. Of these I spoke at some length in a former lecture.

3. The *liver* is very liable to enlargement: either from simple congestion of blood; or from the interstitial deposit of adipous or of lardaceous matter; or from the intrusion of malignant growth; or from colonies of hydatids.

4. So also the *spleen* swells, from fulness of blood, or from specific deposits in its substance.

5. The *kidneys* sometimes attain a vast size; being occupied by malignant disease, or swollen by pus, or by urine, that finds no vent.

6. Enlargements of the *mesenteric glands*; cancerous degeneration of the peritoneum, especially where it forms the *omentum*; tumours connected with the *uterus*; aneurisms of the *aorta*; vast distension of the *gall-bladder*; constitute other species of abdominal swelling, which I simply mention without further comment.

Now our judgment of the character of a given tumour is naturally influenced by its *place*. In the right hypochondrium, we suspect the liver; in the left, the spleen; in the epigastric region, the stomach; in the hypogastric, the womb, or the bladder; in either flank, an ovary, or perhaps a kidney; in the track of the colon, we guess at fecal collections.

But sometimes the situation of the tumour fits more than one, or than two, suppositions. Between the ribs and the ilium on the right side we may have an enlarged ovary, a tumid kidney, a distended cæcum. A prominence in the epigastrium may be due to enlargement of the left lobe of the liver, to cancer of the stomach, to an infarcted transverse colon, to a ventral aneurism. Above the pubes, the distended bladder, or the enlarged uterus, may equally project. The sigmoid flexure of the colon loaded with feces, the left kidney exaggerated by disease, a bulky ovary, may either of them occupy the same sinistral space.

Moreover, the colon deviates strangely, and not seldom, from its natural course and position: and the magnified viscera may invade, by their displacement, or by their irregular expansion, the regions that are proper to other organs.

Our conjectures are assisted by the associated symptoms, and by observation of the regular performance, or of the disturbance, of particular functions. Yet here, also, we meet with continual sources of fallacy. Pressure from a tumour without, as well as infarction within, may impede the passage of alimentary matters through the bowels, of urine through the ureters; and cause, in the one case, flatulence and tormina, in the other, retention or suppression of urine. Growths foreign to the liver may, nevertheless, press upon its excretory ducts, and occasion jaundice. And so of other parts and functions. I mean, that the functions prominently deranged are not always the functions of the part occupied by the tumour, but of organs which are secondarily and accidentally subjected to its disturbing influence. Your sagacity will be abundantly tried in balancing the evidence of different symptoms in these obscure, yet palpable, forms of disease: and after all you will often doubt; and often, when you do not doubt, you will mistake.

Enlargement of the liver may usually be distinguished from other tumours of the right hypochondrium, by *percussion*. Try from the clavicle downwards. At first, you get a hollow sound. Then, a little below the nipple perhaps (for the spot varies much in different subjects) the sound begins to grow dull. If this dulness be traceable, without change or interruption, to the tumour, the inference is strong that the tumour is hepatic. Any other tumour there situate leaves, most commonly, when the patient is recumbent, a palpable sulcus above it; or a space in which the sound, upon percussion, is different from that which is yielded by the liver.

Percussion helps us to discriminate an ovarian from a renal tumour. When the swelling is large, the intestines lie behind the one, in front of the other: and the sound is affected accordingly.

Tumours that are readily *moveable*, are generally intestinal, omental, or ovarian.

A pulsating tumour is not necessarily an aneurism. The healthy artery will lift almost any sort of hard swelling that happens to lie directly over it.

The occurrence of hæmatemesis or of melæna would corroborate your belief that a tumour in the right hypochondrium was hepatic—the left, was splenic.

Even when you are satisfied as to the organ affected, there comes another question, scarcely, in some cases, less difficult than the first—What is the *nature* of the tumour?

Suppose, for the sake of illustration, that your inquiry relates to the liver. If the tumour be large, prominent, smooth, roundish, of slow growth, and the general health be not materially deranged, it is most likely a *hydatid* tumour. If along the edge and upon the surface of the augmented liver, you can feel large inequalities and projections, and if the complexion and general state of the patient are expressive of failing health, the enlargement is, in all probability, *cancerous*; and if there be other

traces of carcinoma in the system, this conclusion becomes almost certain. Small hard irregularities betoken the *hobnail* liver; which is, sooner or later, accompanied by ascites. When, without pain or jaundice, the liver of a phthisical patient transgresses its natural boundaries, it is, presumably, a *fatty* liver, or a *waxy* liver.

By applying a similar method of investigation to other ventral enlargements, you may frequently hit the right scent, and trace the mischief to its true source. To treat the subject in detail would require a volume. I may refer you to a series of papers by Dr. Bright, in the *Guy's Hospital Reports*; where you will find a host of examples, and much valuable information, concerning the most common and the most important kinds of "abdominal tumours and intumescence."

LECTURE LXXXI.

Acute Rheumatism; Symptoms; Varieties: Treatment. Chronic Rheumatism; Phenomena; Plan of Cure.

Gout: Description of a Paroxysm; Progress of the Disease; general state of Health in Gouty Persons; Causes of the Disease; Diagnosis between Gout and Rheumatism.

I PROCEED, this afternoon, to the consideration of that very common, very painful, and sometimes very perilous disease, *rheumatism*. There are two species of it, the acute and the chronic. They graduate, however, insensibly into each other; and the chronic is often a sequel of the acute form. Yet this is not necessarily so. Chronic rheumatism occurs in persons who have had no preceding attack of the disorder in its acute stage or degree.

Rheumatism implies inflammation: but, as I mentioned in an early part of the course, it is inflammation of a peculiar or specific kind. In the first place, it is inflammation of a particular tissue—the *fibrous tissue*: and it may therefore manifest itself wherever that tissue is employed in the fabric of the body. No doubt the inflammation does involve other tissues also: but it is always, probably, by extending to them, through what has been called *contiguous sympathy*. Thus we have the *synovial* membrane of a joint inflamed in many cases, the inflammatory action having spread from the fibrous textures around the joint; or, as I formerly pointed out to you more in detail, the serous surface of the pericardium, and the serous surface (or what is analogous to a serous surface) of the inside of the heart, and especially that part of it which is carried over the valves—each and all of these serous membranes are extremely liable to be affected with inflammation in the acute form of rheumatism; but in all of them it is probable that the *fibrous* texture was the first to suffer. The pericardium is, as you know, a fibrous-serous membrane; and fibrous tissue is interposed between the folds of the serous membrane, in the cardiac valves.

Rheumatism, therefore, is essentially inflammation of the fibrous tissue: and it most commonly seizes upon the fibrous parts that lie around the *larger joints*: the ligaments and the tendons: and in respect to this disease you may almost consider the perpetually moving *heart* as one of the large joints. Yet this inflammation, when confined to the fibrous tissues, is not *common* inflammation. At any rate, it does not reckon among its events (as common inflammation does) either the effusion of plastic lymph, or suppuration, or gangrene. If suppuration sometimes occur (and it certainly occurs very rarely) it is because the rheumatismal inflammation has extended to contiguous textures, and then and there has run the ordinary course of inflammation. The *areolar* tissue around a joint may thus inflame and suppurate. The inflammation of the synovial membrane may be of sufficient intensity to give rise to the formation of pus. When, however, the inflammation extends to the serous tissues within and

around the heart, the products of the inflammation are just the same as when inflammation of the same textures, of the common kind, is anyhow produced.

Acute rheumatism, then, consists in redness, heat, pain, and swelling (that is to say, in inflammation) of the parts lying around, or entering into the composition of, one or more of the larger joints of the body; generally of several at the same time, or in succession; with a disposition to shift from one joint to another, or to certain internal organs, and especially to the membranes of the heart; and with fever.

This tendency to shift its place — to what is usually called metastasis — is a very remarkable feature of the disease. The inflammation will appear, in one joint, suddenly, and as suddenly subside in another which it previously occupied: and then, perhaps, it will jump back again to its old quarters. In very many instances, however, it invades fresh joints without wholly ceasing, and sometimes even without diminishing at all, in those formerly affected. It may visit in this way every large joint in the body, and even seize upon some of the smaller ones; or it may possess nearly all of them at once. It is most commonly seen to affect the ankles and knees, the knuckles, wrists, and elbows. Less often it is seated in the shoulders also; and in the hips. The joints of the fingers frequently suffer; and I have seen more than one instance in which the joints of the jaws were manifestly implicated in the rheumatic inflammation. But by far the most serious and dangerous leap which the diseased action is apt to take, is to the membranes of the heart.

In truth, acute rheumatism is a blood disease. The circulating blood carries with it a poisonous material, which by virtue of some mutual or elective affinity, falls upon the fibrous tissues in particular, visiting and quitting them with a variableness that resembles caprice, but is ruled, no doubt, by definite laws, to us, as yet, unknown.

I pointed out to you, in a former lecture, the symptoms of rheumatic carditis, its consequences, the various ways in which it connects itself with the joint affection, and the treatment by which we are to attempt to moderate it. I dismiss, therefore, this the most momentous complication of acute rheumatism, from the present discussion; and shall confine myself solely to the disease as it manifests itself externally.

The shifting and migratory inflammation of the textures lying around or composing the larger joints, is ushered and attended with high inflammatory fever; with a remarkably full, bounding pulse; with flushed cheeks; head-ache; profuse, drenching, sour-smelling perspirations, which distress and weaken the patient, but bring no present relief to his pain; with a white-coloured, dirtyish, thick fur on the tongue, which is red, however, at its tip and edges; with turbid acid and urine. But this severe and inflammatory fever (*synocha* Cullen calls it) has no tendency to degenerate into a typhus-like form: and that is a striking feature in the complaint. Neither is the intellect affected, except when carditis takes place: and then, as I stated formerly, violent delirium is apt to ensue, misleading the practitioner, drawing his attention away from the chest, where grave and often fatal changes are in progress, and fixing it upon the head, where no inflammation at all exists, but which is disturbed through sympathy with the cardiac disorder. With this exception, we do not find patients in acute rheumatism *delirious*. Throughout all this febrile disturbance, there is no coma, no dulness or bewilderment of aspect, no marked trouble of the stomach or of the bowels, no vomiting, no diarrhoea, no petechiæ, no aphthæ, no *sordes* about the mouth, all which are of ordinary occurrence in the course of common continued fevers. The producing poisons, different in origin and in kind, differ no less in their effects upon the animal economy.

The joints are exquisitely *tender*, as well as painful. The fibrous tissues, which are endowed with but little sensibility in their sound and healthy state, become acutely painful when occupied by inflammation. The pain is increased by pressure; and therefore by whatever implies pressure; by movements of the joints consequently. The patients are reduced to perfect helplessness by the pain; and lie fixed in one position, from which they are afraid to stir. Their common phrase is, that they have entirely lost the use of their limbs: and this is true enough in fact, but not true in the medical sense of those words. They have not lost the *power* of moving them; there is no *palsy*; but they *dare not* move them, because the effort gives them so much torment. They dread the touch of the physician, the handling of the nurse, the shaking of their bed by the footstep of an approaching friend.

As in other disorders which depend upon the presence of some imported or inbred

poison within the body, so also in this—the constitutional symptoms generally precede the local. Nay, I believe that the fever may sometimes run its whole course without any manifest affection of the joints. I have never seen this; but Dr. Graves declares that he had known several instances of persons who, having undergone attacks of genuine acute rheumatism, did afterwards experience febrile symptoms exactly resembling in character, in intensity, and in duration, those which they had previously suffered, although from first to last not a single joint was inflamed.

Pain in the affected joints is more constant than swelling; and swelling more constant than redness. The swelling differs also in different cases in rather a remarkable manner. In fact, two varieties have been made of acute rheumatism. The distinction was first drawn by Dr. Chambers, at St. George's Hospital; and afterwards made public by Dr. Francis Hawkins in his Gulstonian lectures. The varieties are spoken of under the names of *fibrous* or *diffused* rheumatism; and *synovial* rheumatism. I will briefly state their distinctive characters.

In the one, then, the inflammation commences in the immediate neighbourhood of one of the larger joints: not *in* the joint, but *near* it. It attacks the tendons, fasciæ, ligaments, and possibly also the muscles. At first there is not much redness, or swelling: but after the pain has been of some duration, there is a puffiness around the parts affected, caused apparently by turgescence of the blood-vessels, and at length slight pitting, or *œdema*, may supervene, from effusion into the surrounding areolar tissue; and what redness is present is disposed in streaks, following the course of the tendons.

On the other hand, in the synovial variety, which shows itself more frequently and more plainly in the knee than anywhere else, the pain which marks the onset of the complaint does not last long before some degree of swelling is perceptible, together, in most instances, with slight redness of the skin; and this swelling is not due so much to turgescence of the blood-vessels, or to *œdema* of the areolar tissue, as to fluid poured into the *cavity* of the joint. And the form and character of the swelling indicate that it results from the fulness and distension of the synovial membrane. It is tight and elastic, and protrudes, as it were, through the spaces that intervene between the tendons and ligaments by which it is in other parts bound down and restrained: and *fluctuation* is often distinctly perceptible in the superficial joints, when both hands are applied to them.

These are the *local* differences between the two forms of the disease. And there are differences equally well marked between the constitutional symptoms that attend them.

It is in that form which *κατ' ἐξοχήν* is called *fibrous* rheumatism, that the inflammatory fever runs so high; that the tongue is so thickly furred; that the round, full, bounding pulse occurs; that the profuse, spontaneous, acid perspirations break out, which exhaust the patient's strength without alleviating his sufferings; that the urine is high-coloured, and deposits a copious sediment like brick-dust.

In the *synovial* form, the fever is either less intense from the beginning, or soon moderates after the joints begin to swell; the tongue is less foul; the patient sweats much less. It is to this form that the term *rheumatic gout* is often applied. And growing experience has led me to believe, that in this popular appellation the real nature of the complaint is most truly expressed. Gout and rheumatism are very similar in kind: and what has been called synovial rheumatism, while it forms a connecting link between the two, and partakes of the characters of both, is more nearly allied to gout than it is to rheumatism.

Conformably with this belief, it has been noticed that the tendency of the inflammation to settle upon the cardiac membranes is much greater in the fibrous than in the synovial disease. This is a most important difference.

I know of no other exciting cause of acute rheumatism than exposure to cold, and especially to cold combined with moisture. And this is the reason why the disease is very common among the poorer classes of society, who are more in the way of that cause, and cannot guard against it so effectually as their wealthier brethren; among whom it is comparatively rare. The cold probably exercises its injurious influence by checking the elimination, through the skin and other emunctories, of the poisonous principle as it forms, and by thus accumulating it in the blood.

This poison in the blood constitutes that predisposition to the disease, without

which it would never occur. In the absence of the poisonous material, no exposure to wet and cold will produce acute rheumatism; but out of its abundant presence acute rheumatism may and often does arise, independently of exposure to atmospheric vicissitudes, or of any other possible exciting cause. We see it break out in hospital patients who have for some time been protected from such exposure. The predisposition appears to be sometimes inherited. Dr. Fuller tells us that he traced this hereditary character in twenty-nine per cent. of the rheumatic patients admitted into St. George's Hospital. The poison itself is probably a product of unhealthy assimilation.

Acute rheumatism is principally a disease of youth: prevailing most, I believe, from the age of puberty to that of thirty-five or forty. I have repeatedly, however, seen it in children; sometimes as early as the third or fourth year: and I stated to you some time ago, that the chance of the joint affection being complicated with rheumatic carditis is the greater in proportion as the patient is the younger. With, perhaps, two exceptions, I never knew the disease occur in an unequivocal form before puberty, without its being attended with inflammation of the lining or of the investing membrane of the heart.

I have already told you what I believe to be the proper plan of treatment to pursue when rheumatic carditis is present: in that case the affection of the limbs is of secondary consequence. But what are we to do when there is no complication of the joint disease; no invasion of any of the viscera?

Why, if you seek for instruction upon this matter in books, or even among practical men, you will meet with a very perplexing diversity of opinion. Apart from the cardiac affection, acute rheumatism has no *danger* about it; and the articular inflammation usually terminates, sooner or later, in recovery, whether the heart be implicated or not. And most persons who have been for any considerable time in practice have their own favourite method of conducting the disorder to its termination. While many employ free blood-letting, and other active antiphlogistic remedies, some, on the contrary, even in the present day, put their trust in bark. Some give large doses of calomel in the outset of the disease, such as half a scruple or a scruple, with or without a grain or two of opium; and they repeat the dose daily, or oftener, with purgatives perhaps intervening, till the urgent symptoms give way; and in this manner I have seen the disease apparently cut short. But I have also known many instances in which the disease was painful, and protracted, and obstinate, although this practice was adopted early and fairly prosecuted. Some physicians, again, give smaller and more frequent doses of calomel and opium: and some think opium alone to be as useful as this combination. Others depend mainly upon colchicum: others upon large and repeated doses of conium: and some attempt the cure of acute rheumatism through sweating the patient by means of guaiacum, and similar stimulant medicines, and a profusion of bed-clothes.

Now you may be sure—when men's opinions concerning the treatment of a disease which is of common occurrence and easy recognition, are thus unsettled and diverse—you may be sure, first, that no specific for that disease has yet been discovered; and secondly, that the disease is not very obedient, or not steadily obedient, to any remedial plan. When first I began to practise, I pleased myself, now and then, with the belief that I had ascertained the best cure for acute rheumatism; so rapidly and decidedly did the disorder recede and cease upon the administration of such or such a remedy. But, on the next trial of it perhaps, my expectations have been miserably disappointed. This marked improvement has happened under the use of colchicum, of conium, of calomel with opium, of alkalies. I did not, in the prosperous cases, mistake spontaneous recovery for cure. The change was too great and immediate, and the instances of success were too numerous, to admit of that explanation. Whether it be (as I suspect), that slighter diagnostic marks have been overlooked, and that sometimes *gout* has in reality been cured under the semblance of rheumatism—whether bodily idiosyncrasies have withstood the influence of remedies—or whether atmospheric agencies have kept up the disorder in spite of proper treatment—I cannot tell: certain it is that we are occasionally baffled, and the patient continues to suffer, notwithstanding the diligent enforcement of all the approved remedies and plans of treatment, one after the other. I am far, however, from thinking that remedies are useless: and I do by no means assent to the dictum of the first Dr.

Warren, who, when asked what was good for acute rheumatism, replied "six weeks."

One principle to be kept in view in these cases may be laid down broadly and decidedly. That practice will be the best which tends most surely to obviate or to lessen the risk of cardiac complication. Now I believe it to be quite true that the plan of treatment which is most calculated to moderate and to bring to an end the uncomplicated disease, is also the plan of treatment which is the best adapted to the paramount object of keeping it uncomplicated.

In the fibrous or genuine form of the disorder, with the bounding pulse, the flushed face, the high inflammatory fever, you may bleed your patients from the arm; especially if they are young and robust. They will bear to lose a large quantity of blood without fainting; and you will always find the blood drawn to be remarkably buffed and cupped. The pain and inflammation are local; but the case is not adapted to local remedies. We might, by cold applications, be able perhaps to subdue the inflammation in a knee or an elbow: but from the migratory character of the disorder, we should incur the risk, by the use of such topical measures, of repelling the poison into the circulating blood, and of thus giving it afterwards a new and a more serious location.

Venæsection will, almost always, afford a marked degree of relief to the sufferings of the patient: but the relief will seldom be complete or permanent: and we may sometimes with propriety repeat the bleeding. In very few instances, however, can we hope to extinguish the disease, or to reduce its noxious seminal principle within harmless limits, by blood-letting. And this is one of the cases in which you must not take the state of the blood already drawn as a criterion of the propriety of abstracting more. The blood will remain ready to show the buffy coat long after the use of the lancet has ceased to be available or safe.

The advantages of blood-letting in this complaint are, first, the partial relief which it bestows. It is seldom that the pain is not sensibly mitigated, and the fever calmed, provided the bleeding has been carried to a proper extent, sufficiently soon. Secondly, free and early venæsection may sometimes perchance (but not often) cut short the attack. This, however, is a favourable effect which you must not reckon upon, and which I would not advise you to aim at. But, in the third place, blood-letting may be serviceable, by preparing the body for other remedies: for calomel, opium, purgatives, colchicum.

Yet, looking to my own practice in acute rheumatism, I find that although I am in the almost daily habit of treating it—for it is a disorder from which our wards are never perhaps entirely free—I rarely prescribe phlebotomy. Many of the patients come under our care at an advanced period of the disease; when the time for bleeding, with any prospect of benefit, has gone by. Some have been bled before their admission. Others, in whom the rheumatic diathesis has become inveterate, are suffering recurrences of the malady: and neither does the recurrent disease require, nor would the system bear, active and repeated depletion. In many instances, again, the constitution has been battered and broken by a London life: while in others there is no great intensity of febrile disturbance from the first. So that the cases in which I am tempted to employ the lancet are really few and far between. At the same time I can well believe—what I have often heard—that in the country, in young persons of unimpaired vigour, in the first attacks of the disorder, and when the inflammatory symptoms run high, venæsection may be of much service in mitigating the sufferings of the patient, and in facilitating his cure.

In all diseases in which pain is a prominent symptom, opium is a most serviceable and precious remedy. In rheumatism pain is a very prominent symptom. It is severe, it is multiplied by its occupancy of many parts at once, it is apt to continue long without any natural pause or abatement, it prevents sleep. You will find it right, and even necessary, to administer opium in almost every case of acute fibrous rheumatism. What should be the dose, and how frequently it should be repeated, must be regulated by its observed effect. Enough must be given to quell, or to assuage the pain. Dr. Corrigan, of Dublin, trusts to opium alone for the cure. He begins with one grain, and repeats that quantity at short intervals, or increases it, until sensible relief is obtained: and he then continues the dose thus reached, up to the time when the disease is manifestly departing. Dr. Corrigan found twelve grains in the twenty-

four hours to be the average requisite amount: but less than even one half of this quantity will generally suffice when other remedies are combined with the opium.

I believe few persons now adopt the plan of forced perspiration for the cure of acute rheumatism. Formerly it was the fashion to give powerful sudorifics: Dover's powder, or antimony, in large doses: and the patient was "accinctus ad sudorem;" covered up in bed between thick blankets, with a hot bottle or brick at his feet. But in the severe, unequivocal fibrous form of rheumatism, the perspiration is profuse without any artificial means being used to excite it, and it is not accompanied by the smallest alleviation of the pain: nay sometimes the patients will tell you that they are worse, in that respect, while the sweating continues.

The preparations of colchicum have sometimes, whether venæsection has been premised or not, an almost magical effect in subduing the disease. Frequently, when most successful (though that is by no means a necessary condition of their success) they exercise some marked influence upon the stomach and bowels. Colchicum is very apt to occasion deadly nausea and vomiting, griping, and diarrhoea, and when these consequences ensue from its use, the inflammation of the joints often subsides entirely. At any rate, if the rheumatism do not give way when the stomach and bowels become thus affected, you may be certain that to push the colchicum further would be useless.

Our wishes, however, and our expectations, from colchicum, are often doomed to be defeated. I believe that in proportion as the synovial symptoms predominate, or mix themselves distinctly with the fibrous—in proportion as the disease approaches in its characters to gout—you may expect to be successful with colchicum. Large doses are not requisite. Twenty minims of the wine or of the tincture may be given every six hours, until some result is obtained. Or a grain of the inspissated juice, or of the acetous extract of colchicum, every four hours. Under this treatment the disease sometimes vanishes within three or four days; the medicine producing sickness and purging, and the rheumatism, or the rheumatic gout, rapidly declining. Occasionally the same favourable event takes place, although there has been no disturbance of the stomach or bowels.

Much and prompt amendment may often be effected, at the outset of the disease, through full and free purging, exacted from day to day by means of calomel and black draughts. From five grains to a scruple of calomel given every night, and followed every morning by a draught of senna and salts, will sometimes obtain and dislodge a vast amount of dark and foul secretions from the liver and bowels, and bring sensible relief to the patient's sufferings. And these doses, adjusted to the particular circumstances of the case, may be repeated for three or four days in succession, provided that they continue to procure dark evacuations, and that their operation is unattended with griping pains, a scalding of the rectum, or the discharge of mucus or of blood.

This practice was first followed and taught by Dr. Chambers; and its beneficial results, when it is beneficial, are so early and so marked, that it has become a common and a favourite practice. It is not, however, always an eligible practice. Persons of a weakly habit of body—persons in whom the disease has already run on for some time—do not bear this course of hard purging. There is also a practical evil in the exaction of four or five motions from the bowels of these rheumatic patients every day; I mean the inconvenience, the increase of pain, and the exposure to cold, occasioned by frequently going to stool; and this is a disadvantage likely to be particularly felt in *hospitals*.

Sometimes it is expedient, in the prosecution of this plan, to combine with the calomel a grain or more of opium; both with the view of quieting pain, and of preventing the calomel from running too rapidly through the bowels. For, besides its operation as a purgative, the full influence of the calomel upon the biliary and intestinal secretions is essential to its curative effect upon the disorder.

Again, there are cases of acute rheumatism which proceed kindly, or yield readily, under moderate doses of calomel and opium, repeated every six or eight hours, with occasional purgatives of the milder kind.

The acid properties of the perspiration, as manifested by its peculiar odour—of the saliva, as tested by litmus paper—of the urine, as shown by its deposits—warrant

the belief that the peculiar poison, which the whole disorder would seem to be an effort to discharge from the blood, is some sort of *acid*. And reason suggests the likelihood of benefit from attempting to facilitate the escape of this poison, to draw it forth from the system, or to neutralize its noxious qualities. Now the bloodletting plan, and the purgative plan, both tend to aid the removal of the poisonous element; but when carried beyond a certain point, or when applied inopportunately, they bring evils of their own. *Alkaline* drugs would appear to be chemical antagonists of the poison; and they have the further good effect of hastening its ejection through a natural emunctory, inasmuch as they are most of them diuretic. Accordingly the treatment of acute rheumatism by alkalies is also, and long has been, a common and a favourite treatment among physicians. Nitre in large doses has been much used and commended; and the alkaline carbonates are very generally prescribed. The bicarbonate of potash in solution has been largely and fairly tried by Dr. Garrod, who has administered it in the average quantity of two scruples, repeated every two hours, by night and by day, for several days together. Of 51 cases so treated, the average duration under treatment was between six and seven days, and the average duration of the whole disease was between thirteen and fourteen days. The medicine soon rendered the urine alkaline. It had no injurious influence on the bowels, or on the bladder. It seemed rapidly to calm the pulse, and to allay the febrile heat. In no instance did any affection of the heart arise after the patient had been forty-eight hours under its influence.

It is an additional recommendation of alkaline remedies in this disease, that they hinder (if we may trust the medical chemists) the deposit of the fibrin of the blood, and may therefore be regarded as so far tending to prevent the formation of endocardial vegetations. The alkaline carbonates may be prescribed in the pleasant form of an effervescing draught, containing an excess of 30 or 40 grains of the carbonate; the dose being repeated every three or four hours while the fever runs high, and the joints are swollen and painful.

The favourite drug of the late Dr. Golding Bird in this and in some other blood-diseases, was the *acetate of potass*. This intelligent physician was himself more than once the subject of acute rheumatism, and his testimony to the efficacy of the acetate is so strong and direct that I cannot forbear quoting it. "I would not willingly (he says) use language which was not completely compatible with experience, but I do not still hesitate to declare that I have never seen the disease in question yield with so much facility to any other remedy. In the severest cases which have been admitted into the hospital under my care, I have seen the cure to be more rapid, and the immediate relief to the patient more marked, by the use of the acetate of potass in quantities of half an ounce, administered, largely diluted, in divided doses, in twenty-four hours, than by any other treatment. In three days I have repeatedly found the exquisite pain of the joints nearly absent, the patient comparatively comfortable, and able to bear with greater ease the helpless state in which the still swollen joints place him. In no case has any ill effect followed the use of the remedy, and whilst the cure has been far more expeditious, the ill effects of colchicum and mercury have been avoided. The pain remarkably and suddenly lessens as soon as the urine becomes alkaline and rises in specific gravity. I can indeed unhappily attest my experience in my own person on the marked alleviation and rapid cessation of the pains of rheumatic fever from the use of the drug, and can gratefully compare its influence with the tedious and painful results of mercurial treatment in a former attack. It is difficult to decide on the comparative immunity from pericarditis in acute rheumatism under particular modes of treatment, but the impression on my mind is very deep, that the tendency to this fearful complication is very much lessened as soon as the urine is rendered alkaline by the acetate." He was in the habit of administering it "in some aromatic water, or what is far more grateful, in plain water, to which a few drops of oil of lemons have been added."

Alkalies, then, or the alkaline salts, are always, in my opinion, fit remedies to be employed in the treatment of acute rheumatism. They may be added largely to the common effervescing saline draught, or they may be simply dissolved in water. Together with them, blood-letting, calomel, purgatives, opium, colchicum, may be variously combined, according to the special circumstances of the case. And what those spe-

cial guiding circumstances are, may be gathered, I trust, from what has been already said respecting these remedies separately.

You will take into account the age and strength of the patient, the period of the disease, the degree of heat and fever, the condition of the pulse, the preponderance of pain, the state of the abdominal secretions. You will bear also in mind that in proportion as the disease assumes the synovial form, the nearer it approximates in its characters to those of gout, the less energetic should be the treatment, and the greater is the likelihood that the preparations of colchicum may prove a useful part of it.

In the tenth and eleventh chapters of his *Lectures on Diseases of the Heart*, Dr. Latham has given a masterly analysis of the purpose, and the effects, of the main remedies for acute rheumatism, both in their separate use, and in their various combinations. He shows how, in one case, venesection may suffice, by subduing high vascular action and febrile heat; how, in another, opium may solve the disease, by allaying nervous disquietude and pain; how calomel and purgatives, in a third, may cleanse the liver and bowels, and the whole system, of a colluvies of morbid secretions, and so set the sufferer free; and finally, how, in most instances, these three remedial measures may together, or with the occasional interjection of colchicum, achieve the desired end more certainly, and with less of distress, and of expenditure of vital power, than could either of them singly. The skill to deal practically with the varying exigencies of particular cases can be learned nowhere but by the bedside of the sick, under the guidance of competent teachers; but I am sure that a careful study of these admirable lessons will greatly help your choice of remedies, and simplify your conceptions of their proper aim, and contribute to form your judgment of their real efficacy.

Bark used to be highly thought of for the cure of acute rheumatism; but it is beneficial, or safe, only during the convalescence. Where the system has been much reduced and broken by the complaint, or by the discipline the patient has undergone, I think that the decoction of cinchona is of service in fortifying the body against the renewed agency of those causes on which the original attack depended.

Respecting guaiacum, the iodide of potassium, lemon-juice, all of which have been lauded as curative of acute rheumatism, I can tell you nothing from my own experience.

Of external remedies in relief of the articular *pains*, less use has been made than might well have been made. The affected joints rarely sustain any permanent damage. The inflammation is apt to leave them of its own accord, even suddenly, and sometimes as suddenly to return. Leeches, or cupping-glasses, would seem therefore needless, or superfluous. Repulsion of the poison which is making its exit through a joint, back again into the circulating blood by cold applications—to settle possibly upon some internal part, and especially upon the heart—would be positively hazardous. No peril, however, of this sort belongs to *warm* fomentations, which often afford exceeding comfort. Both Dr. Basham and Dr. Fuller have fairly ascertained their safety and their value. Theory suggested that the lurking or emerging poison might be neutralized and rendered innocuous by making these fomentations *alkaline*, and experience appears to confirm this notion. I may quote Dr. Fuller's remarks on this subject. Warm fomentations "soothe the parts, promote perspiration, and thereby favour the elimination of the poison. As the object of the application is to allay the pain, and to counteract the extreme acidity which always accompanies if it be not the cause of rheumatic inflammation, it is manifest, theoretically at least, that an alkaline and opiate solution should prove the most effectual remedy. And so in practice it is found to be. I have tried hot water; I have tried a warm solution of nitrate of potash, as recommended by Dr. Basham; I have tried a simple alkaline solution; and I have tried a mixed alkaline and opiate solution, and the latter has proved far the most powerful in allaying the pain of rheumatic inflammation. In every instance in which it has been employed, the relief obtained has been almost immediate. In order to guard against any source of fallacy, I selected fourteen instances in which corresponding joints were affected, and applied a fomentation of warm water to the one joint, and an alkaline and opiate solution to the other, and almost uniformly the pain and inflammation continued in the former, and speedily subsided in the latter."

The solution usually employed by Dr. Fuller is made by dissolving half an ounce

or six drachms, of the carbonate of potass, or of soda, in nine ounces of hot water, and adding six fluid drachms of Battley's *liquor opii sedativus*. Thin flannel, soaked in this hot lotion, is applied to the inflamed joints, and the whole is wrapped in a covering of thin gutta percha.

Cases frequently occur which are neither absolutely acute, nor absolutely chronic. The inflammation, without being intense in any one joint, lingers in many; and the fever, though not entirely absent, is moderate. The joints are hot and painful, and the skin is dry, and there is some thirst. To this intermediate character the term *sub-acute* is sometimes applied; and it will serve our purpose of distinction.

In this form of the disease, as well as in the more active form, the urine is almost always loaded with lateritious matters, and strongly acid. Looking upon this as an indication of treatment, I have prescribed alkalies, and with much success: the liquor potassæ, for instance, to the amount of a drachm daily, for several days together; keeping the bowels free by laxative medicine. Under this plan, more surely in my experience than under any other, the urine clears, the pain abates, and the joints are liberated. Nitre, I repeat, has been praised of late as being eminently successful against rheumatism: I have not had much opportunity of trying it, but I should think it likely to do good in these subacute cases.

There are two kinds of *chronic* rheumatism: one attended with local heat and swelling, although the constitution at large sympathizes very little or not at all with the topical inflammation; the other characterized rather by coldness and stiffness of the painful joints. In the former of these the pains are increased by pressure, and by movements of the limbs, and by external warmth; the warmth of a bed, for example; and there may be even some slight degree of pyrexia at night. In truth this form of chronic rheumatism claims a near relationship with the acute, *into* which it sometimes passes, and *of* which it is frequently the sequel. It accordingly requires antiphlogistic remedies, only less vigorously applied. It is important for you to know that, in these cases, you may, with less hesitation, less fear I mean of driving the inflammation to some more vital part, apply leeches, and cold washes, to the painful joints. Otherwise, the principle of treatment remains unchanged. The complaint is, however, often obstinate and lingering, and prone to recur. It frequently involves and cripples the smaller joints, especially those of the knuckles and fingers; rendering them knobby, and distorting their form and position. The fingers take a permanently oblique direction, slanting outwards towards the ulna: and Dr. William Budd has drawn attention to the curious fact that the corresponding joints of the two sides of the body are always affected exactly in the same manner. To use a paradoxical expression, the deformity is symmetrical. One crooked joint is just the copy of its fellow. Surely this indicates the *constitutional* origin of the disorder; the infection of the *blood*.

In the other form of chronic rheumatism, what some call *passive*, the remedies that answer best are of a different kind. The pain is alleviated by friction of the joint, and the patients are most comfortable when they are warm in bed, and especially when moderate perspiration is present. They are singularly benefited also by summer weather. Persons who are much troubled by this wearing complaint, and who can afford to live where they please, would do well to take up their residence in a warm climate. Wherever they may be, such patients should be protected against atmospheric vicissitudes by warm clothing: they should be cased in flannel from the neck downwards. Warm bathing is of great service; and especially baths of salt water, of a temperature not less than 100°, that they may act as a stimulus to the cutaneous circulation; warm douches; the vapour bath; or the hot-air bath, of which, as I said before, the patient may receive the benefit as he lies in bed. And to warm clothing, and warm bathing, may be added friction, with some stimulating liniment, and what is called shampooing. It is in these cases that stimulating internal medicines are often of use. Turpentine; some of the animal oils, the cod's-liver oil for instance; guaiacum. Opiates, too, are frequently remedial of the pain; and there can be no better form for their administration than that presented to us in the celebrated Dover's powder; the *pulvis ipecacuanhæ compositus* of the Pharmacopœia.

Whatever its value may be as a remedy for acute rheumatism, the iodide of potassium is certainly available for the relief of the chronic disorder. It is *most* sure to

act beneficially when that fibrous part, the *periosteum*, is principally affected. Its virtues in the case of venereal nodes (*i. e.* in venereal inflammation of the periosteum) were first distinctly pointed out by Dr. Robert Williams, of St. Thomas's Hospital. I believe it is equally effectual, upon whatever cause chronic inflammation of the same part, with nodes and thickenings, may depend.

Some of you probably saw a woman who was lately my patient in the hospital, and who had been worn down to a skeleton by the pain she had endured from chronic periostitis giving rise to nodes, which did not appear to be traceable to syphilis. She had been in the habit of lulling the pain by large opiates at night, and begged to have them after her admission. I gave only the iodide in the ordinary dose (five grains thrice daily), and she slept without opium; and in a week or two lost her nodes, and was perfectly well.

Closely allied to acute *rheumatism*, and yet distinct from it, is the singular disease which in this country is popularly called the *gout*: which Cullen, in the first instance, was disposed to term arthritis; but as arthritis would imply inflammation of all or any of the joints, he afterwards adopted the ancient name of *podagra* (foot-pain).

The same author has given, in his *First Lines*, an excellent account of the phenomena which constitute a paroxysm of gout. It is copied from Sydenham, who drew from nature; for he had himself suffered frequent and severe visitations of the disease during a period of thirty-four years.

The attack begins, most commonly, an hour or two after midnight. The patient, who had gone to bed and to sleep in his usual health, and without suspecting what was about to happen, is awakened by a pain in one of his feet, mostly in the first joint or *ball* of the great toe; but sometimes in other parts of the foot—the heel, the instep, the ankle. With the coming on of this pain there is generally more or less of a cold shivering, which gradually ceases as the pain gets worse, and is succeeded by heat. The pain grows more and more violent and intolerable; and is spoken of by those who suffer it as amounting to torture. It is a grinding, crushing, wrenching pain; or a burning sensation as if a hot iron were pressed into the joint. Some humorous Frenchman described it in this way. “Place (said he) your joint in a vice, and screw the vice up until you can endure it no longer. That may represent rheumatism. Then give the instrument another twist, and you will obtain a notion of the gout.” The pain is attended with great restlessness and misery, and exquisite tenderness. The patient cannot bear the weight of the bed-clothes upon the affected limb; nor the jar of a heavy foot-fall in his chamber. In a vain search after comfort he is perpetually shifting his foot from place to place, and from posture to posture. At length, about the ensuing midnight, the pain remits; sometimes gradually, sometimes so suddenly that the patient attributes the relief to his having at last found an easy position. He falls asleep in a gentle perspiration, and when he awakes the next morning he finds the part, which had been so painful, to be red, swelled, tense, and shining, surrounded by more or less œdema, and by turgid veins. The same series of symptoms recur, in a mitigated degree, for some days and nights; and then the disease often goes entirely off, not to return till after a long interval.

As the œdema subsides, and the redness fades, the cuticle of the part that has been inflamed peels off; and this process of desquamation is generally attended with troublesome itching.

Such is a picture of an attack of gout, occurring in an adult subject, for the first time, and in its most regular and genuine form.

Attacks of this kind are preceded, in most instances, by some marked disorder of the functions of the stomach; diminished appetite, flatulence, heartburn, nausea perhaps. And during the paroxysm the urine is often dark-coloured, and acid, and turbid; depositing copiously a pink, or brick-dust sediment. The stools, also, are unnatural; pale, or of a dark green, and very offensive. After the fit, when the complaint has ceased entirely, it generally (says Cullen) “leaves the person in very perfect health; enjoying greater ease and alacrity in the functions of both body and mind than he had for a long time before experienced.”

But the disorder, which has thus departed, is very apt—nay, unless extreme care be taken to prevent it, and even in spite of all care, it is almost sure—to return. At first, perhaps, it recurs not oftener than once in every three or four years; but after

some time the intervals are shorter, and the attacks become annual, happening about the same time of the year: afterwards they come twice every year; and at length they return several times during the course of the autumn, winter, and spring. And as the fits are more frequent, so also are they more protracted, till, in the advanced state of the disease, the patient is hardly ever free from it, except perhaps for two or three months in summer. I do not mean that all this occurs invariably in all cases alike; but this is a sketch of the general course of the complaint.

There are other phenomena also to be noticed as time advances, and as the disease is repeated. At first, I say, it commonly appears in one foot only; afterwards every fit includes both feet, the one after the other; and as the disease continues to recur, it not only attacks both feet in succession, but after having ceased in the foot which was secondly visited, it will return again into the foot first affected, and perhaps a second time also into the other. It passes, too, into other joints, both of the upper and lower extremities, large as well as small; so that there is scarcely a joint that may not, at one time or another, be seized upon. But as the disease proceeds, and the fits get to be more numerous, the pains are commonly less violent than they were at first; the patient is, however, more affected with sickness, and suffers more in his general health.

Again, after the earlier attacks, the joints usually recover entirely their former strength and pliancy; but when the disorder has returned again and again, they are not so readily nor so completely restored to their previous condition, but remain weak and stiff: and sometimes they lose at length their capacity of motion altogether.

Also, in many gouty persons, but not in all, after the disease has frequently recurred, what are called *chalk-stones* form; concretions, that look exactly like chalk, collect around and outside the joint, filling up the areolar tissue, and lying, in general, immediately beneath the skin. The material of these curious concretions is deposited at first in a half fluid state, and resembles soft mortar; but the more watery ingredients being afterwards absorbed, it becomes dry and hard. Of course when this stuff is deposited in any quantity on the outside of a joint, it must to some extent limit, or it may entirely prevent, the motion of that joint. The concretions consist mainly of the urate of soda, in a crystalline form. The cartilages *within* the joints are also sometimes encrusted with this salt; and Dr. William Budd has ascertained that the crystalline deposit is not merely spread superficially over the free surface of the cartilage, but penetrates a little way into its substance. Another, and an odd place, in which these deposits are extremely common in gouty persons, is the cartilage of the external ear.

Gout is a disease that was well known, and well observed, by the ancients. In its genuine form it could neither be overlooked nor mistaken. Many very interesting facts relative to this painful disorder have accordingly been ascertained: and I proceed to notice the chief of these; but I must do so with as much brevity as I can.

First, then, gout is a *hereditary* disease. I do not mean to say that the disposition to it is always a transmitted disposition; but that the complaint is much more likely to occur in persons in whose pedigree it can be traced, than it is in other persons. It may, I believe, be generated by certain habits of life; and, on the other hand, in spite of an inherited predisposition, the disease may be staved off and averted. Let the son of a rich and gouty nobleman change places with the son of a farm-servant, and earn his temperate meal by the daily sweat of his brow; and the chance of his being visited with gout will be very small. Granting this, we see reason, independent of the general analogy of hereditary disorders, why the gout may be expected sometimes to leap over a generation, just as family likenesses are known to intermit; while yet the *disposition* may descend to the children of those who, in their own persons, have never suffered the *disease*. Among 522 gouty persons, concerning whom Sir Charles Scudamore had collected information, 332 could trace their disease to the father, mother, grandfather, grandmother, uncle, or aunt. In the remaining 190 the disease was not known to have existed in either upward branch of the family-tree.

2. There is a pattern of body which is believed to be favourable to the acquisition of gout. "It attacks (says Cullen) especially men of robust and large bodies, men of large heads, of full and corpulent habits, and men whose skins are covered with a thicker *rete mucosum*, which gives a coarser surface."

3. Whether, in a given individual, there be an inherited tendency to the disorder

or not, its access is promoted in a remarkable manner by a full and luxurious mode of life, and by sedentary or inactive habits.

4. It is observed of gouty persons, that they are usually subject to nephritic complaints also, to fits of the gravel, to renal and vesical calculi. These disorders of the urinary organs commonly begin to manifest themselves after the gout has plagued the patient for some time. They do not coincide with the paroxysms of gout, but the two happen alternately: or (what is equally expressive of the connexion between the two forms of disease) the children of gouty and nephritic parents inherit often the one or the other of these maladies; but "whichever may have been the principal disease of the parent, some of the children have the one, and some the other. In some of them the nephritic affection occurs alone, without any gout; and this frequently happens in the *female* offspring of gouty ancestors."

The urinary concretions to which gouty people are so subject, and the morbid states of their urine generally, belong to the *lithic* diathesis. Dr. Prout holds that the lithic or uric acid, developed principally during the mal-assimilation of the albuminous textures, may be considered as the characteristic feature in gout." And the chemical composition of the *chalk-stones* which sometimes accompany gout, is in accordance with this statement; and illustrates strongly the connexion between gout and gravel. The so-called chalk-stones are chiefly composed, as I have said before, of uric acid combined with soda; of the urate of soda. Sometimes this very urate of soda, perfectly white, is deposited in large quantities in the *urine*. Dr. Prout says that he has seen it copiously secreted of the consistence of mortar, so as to block up the urethra in its passage outwards. Now this is just the stuff which is deposited around, and sometimes within, the joints, and which hardens and crystallizes as it collects. I may mention here again that many persons have the gout long, and severely, without having any of these concretions. They are incidental to the more chronic forms of the disorder, in which the pain and the fever, though of long duration and frequent recurrence, are slight in degree. The cuticle at length gives way, and the earthy matter lies bare. A namesake of mine, Mr. Henry Watson, describes in the first volume of the *Medical Communications*, the case of a Mr. Middleton, who was accustomed, when playing at cards, to chalk or score the game upon the table with his gouty knuckles.

5. Gout attacks especially the male *sex*. Some few women, however, suffer it, in its regular and decided form; and generally these women are robust and plethoric. Cullen noticed its occurrence in "several females whose menstrual evacuations were more abundant than usual." But in women the disease chiefly happens after the catamenia have ceased to appear. Heberden knew a female who had numerous sores from chalk-stones.

6. Cullen observes that the gout does not usually come on till after the *age* of five and thirty. Heberden, who in his long and extensive practice among the higher classes of society in this town saw as much, perhaps, of this disease as any physician ever did, says that he never met with a case which he could decidedly pronounce to be gout, before the age of puberty. Sir Charles Scudamore has collected a statistical account of 515 examples of gout, in which the period of the first assault had been noted. Of these 142 began between the ages of 20 and 30; 194 between 30 and 40; and 118 between 40 and 50. The greater number, you will observe, was between 30 and 40.

However, I believe that where the inherited disposition is strong, and the habits of living are such as to foster that disposition, gout may show itself, occasionally, even prior to the age of puberty; but this is, certainly, the exception to a very general rule.

7. Gouty persons are subject to various ailments, which spring from the same fountain as the well-marked paroxysm: derangements in the functions of the digestive organs, of the heart and lungs, of the brain and nerves.

The most familiar of these ailments is indigestion, with its various circumstances of impaired appetite, sickness, vomiting, flatulency, heartburn, acid eructations, gastrodynia. Pains and cramps occur in several parts of the trunk, and shoot thence into the upper extremities, and are relieved upon the extrication of wind from the stomach. The bowels are irregular; colicky diarrhoea being sometimes the prevailing fault, but more commonly costiveness. With all this the patient is apt to be exces-

sively dejected and hypochondriacal, morbidly attentive to every bodily feeling, disposed to exaggerate his sufferings, and apprehensive of the worst event.

When the viscera of the thorax are affected, the patient has palpitations, fits of dyspnœa, faintings, or even pangs like those of angina.

In the head occur pain, giddiness, transient affections of the vision and of the hearing, threatenings of palsy and apoplexy.

All these, you may say, are feelings and ailments to which any and all persons are liable. True: but the remarkable peculiarity which connects them, in some men, with gout is this: — that they often all clear away and disappear upon the breaking out of a paroxysm of that disease in the foot.

Hence such symptoms are regarded as indicating one variety of *irregular* gout. Cullen, led by a questionable theory, classes them under the head of *atonic* gout. Sometimes the patient so affected is said to have *lurking* gout; or *masked* gout.

In another variety of irregular gout, the complaint commences, in the ordinary way, in a joint; but the pain and inflammation do not reach the ordinary degree of intensity, or at any rate do not continue for the usual time and then recede gradually in the accustomed manner, but they disappear abruptly and entirely, while symptoms of severe and alarming disorder arise, as suddenly, in some internal part. This Cullen names *retrocedent* gout. It affords an example, as I conceive, of true metastasis. The internal part most commonly attacked is the stomach. It becomes affected with a peculiar feeling of anxiety and distress; with sickness, vomiting, or violent pain which the patient calls spasm, and which perhaps is of a spasmodic character. More rarely the retrocession is to the heart, when syncope or urgent dyspnœa ensue; or to the head, when it may terminate in a stroke of apoplexy, or of paralysis.

In a few cases the disorder, thus alighting on some other part than a joint, is plainly inflammatory. The most common example of this is gouty inflammation of the urethra, with scalding and a puriform discharge; simulating very exactly an attack of gonorrhœa. So also there is a gouty form of ophthalmia, or gout in the eye; gout in the testicle; and a year or two ago an eminent physician of my acquaintance suffered a violent and dangerous attack of what was considered to be gout in the throat. Dr. Cullen speaks of these inflammatory affections under the title of *misplaced* gout: but they may well enough be ranked under one of the preceding heads of masked, or of retrocedent gout.

The disposition to gout may be engendered, and when inherited will infallibly be strengthened and developed, as I have told you already, by certain habits of life: by sensual indulgences, and (but in a less degree, I believe) by want of bodily exercise. Of this we have the strongest negative evidence in the remarkable immunity from the disease enjoyed by the working poor in our rural districts. One never hears of the gout among agricultural labourers. Sir Gilbert Blane states that, during ten years in which he was physician to St. Thomas's Hospital, although in his private practice he reckoned 130 patients who had gout, being about one in twenty-six of the whole number, he had not a single case of it among 2406 patients in the hospital. This I think strange, for in the London hospitals it is not very uncommon for us to meet with gout; but then it is in persons who have lived fully and inactively: in the servants of wealthy families for instance, butlers, coachmen, porters — men who often live more luxuriously, and more idly a great deal, than their masters. And among the rich, those who are most subject to gout are notoriously those who indulge most in what are called the pleasure of the table; who eat largely of animal food, and drink much wine: especially if they are indolent withal. Such men generate for themselves the lithic acid diathesis; and if the gouty tendency happen to have been born with them, they incur the disease, under these habits, with more or less readiness, according to the degree of that innate disposition. Strong exercise certainly *remedies*, in some measure, the evil effects of this mode of life, by promoting the excretions of the body: but gout used to be exceedingly common in the old-fashioned fox-hunter, who "rode hard," while he also "lived hard." Mere sedentary habits do not produce gout, as we learn from the comparative exemption of females; and of the poor, who, following sedentary employments, are yet compelled by their poverty, which is so far a blessing to them, to be temperate. Men who eat much meat, generally indulge themselves in drinking also: the two causes go together, and it is diffi-

cult to estimate their separate influence. Butchers, who live fully upon animal diet, are said to be rarely affected with gout, but then they necessarily take a great deal of exercise. It appears that the use of wine, and of malt liquors, fosters the disposition to gout much more than the abuse of distilled spirits. The paucity of gouty patients among the lower classes in this gin-drinking town suffices to show this. I have been told that gout is very little known in Glasgow, where the commercial men live richly, and lead sedentary lives, but do not drink much wine, their favourite beverage being rum-punch, of which they are not at all sparing. Dr. William Budd says that the disease is common among the "ballasters" on the Thames; that, although they are not a numerous body, many are admitted with gout every year into the *Dreadnought*. Now these men being much exposed to inclemencies of weather, and using great bodily exertion, which is attended with profuse sweating and much exhaustion, think themselves warranted in drinking (besides spirits) two or three gallons of porter daily. This shows the effect of malt liquor in producing the gouty habit of body.

On the other hand, the inbred gouty tendency may be so strong, as to be scarcely kept in check by the most abstemious regimen.

A fit of the gout may be *brought on* by various circumstances: in other words, the possible *exciting* causes of gout are many. A paroxysm has been frequently known to follow immediately upon an unusually severe debauch. Strong mental emotion has sometimes the same consequence, especially emotion of a depressing kind. Excessive fatigue—more particularly fatigue produced by too much walking exercise on any one day—is another exciting cause. And this is unlucky, for it often discourages a patient from again making use of a proper and even a necessary amount of exercise of that kind. Another exciting cause which frequently operates is external injury. The first attack of gout often fixes upon the seat of an old hurt: and a very slight recent injury is sometimes enough to determine a paroxysm—a trifling bruise, or sprain, the pressure of a tight shoe; nay, Dr. Heberden tells us that he verily believes he has seen an attack of gout brought on by the bite of a flea; showing how easily the disease may be excited, when there is a strong predisposition to it. This it is which makes us so often doubt the accuracy of gouty persons, when they tell us that they are lame from a mere sprain.

Dr. Cullen enumerates sundry debilitating circumstances, which, as such, appear to operate in calling into action the gouty disposition. And there can be no doubt that a state of weakness does often favour the eruption of the malady. A friend of my own had lately a most serious attack of continued fever, in the course of which he became hemiplegic, and his life was despaired of. Soon after the fever had left him, and while he was yet extremely feeble, he had three attacks of gout in quick succession.

Plans have been taken by several writers, especially by Heberden, to lay down the distinguishing characters between gout and rheumatism. A first assault of gout can scarcely be confounded with an attack of acute rheumatism. The limitation of the inflammatory redness to one foot, and the restless distress of the gouty patient, contrast strongly with the helpless and motionless condition of the rheumatic, who is pinioned, so to speak, in many limbs. There may be more room for doubt and mistake in the advanced state of gout, when many joints have at length become involved; but even then you may generally decide by inquiring into the history of the patient, and learning the circumstances of his early attacks.

The main points of distinction may be broadly and generally stated thus.

In gout the small joints are first and chiefly affected, especially the joint of the great toe: in rheumatism, the large. The redness of the gouty inflammation is more bright and vivid than that of the rheumatic; and the fluctuations between agony and ease are more complete and more frequent. Gout usually affects one joint only at a time: rheumatism usually several at once. The inflammation in gout is attended with turgid veins, and with more œdema than in rheumatism; and is followed, in the majority of instances, by desquamation and itching, phenomena which we do not notice at the close of rheumatic inflammation. Gout is not attended with those drenching acid sweats which are so characteristic of acute fibrous rheumatism. The gout is decidedly hereditary: rheumatism, though probably hereditary too, is much less distinctly so. The gout occurs rarely or never, whereas rheumatism is not very

uncommon, before the age of puberty. In gout, though many functions suffer, and especially the digestive functions, there is no tendency to carditis: in rheumatism, with far less general disturbance, but more fever, that tendency is very marked. Gout is often, rheumatism is never, associated with chalk-stones: and conformably with this distinction, Dr. Garrod has taught us that uric acid in excess is present in the blood of gouty, and not present in that of rheumatic patients. Gout is the punishment (some have thought it the privilege) of the rich, of persons who live fully, luxuriously, and indolently: rheumatism is most frequently the appanage of the poor, and of those who toil.

LECTURE LXXXII.

Pathology of Gout. Prognosis. Prejudices respecting the disease. Treatment: during the paroxysms; during the intervals. Cutaneous Diseases.

I YESTERDAY described the phenomena of gout, from its primary outbreak to its crippling consummation. I told you what observation has collected concerning its causes; and I pointed out the circumstances which distinguish it from rheumatism. Let us look a little closer into the essence of this curious malady.

The pathology of gout has been the theme of endless controversy. Humoralists and solidists contend alike for the triumph of including the disease within the pale of their respective theories. The very name, *gout*, derived through the French *goutte* from the Latin *gutta*, expresses summarily the doctrine of those who imposed it: and we trace the same, or a similar idea, in the appellation of the kindred disorder, *rheumatism*.

“The opinion (says Cullen) which has generally prevailed, is, that gout depends upon a certain morbid matter, always present in the body; and that this matter, by certain causes thrown upon the joints or other parts, produces the several phenomena of the disease.”

You will find this doctrine at the bottom of all Sydenham's speculations on the subject. But Cullen doubted it, and even endeavoured, in an elaborate argument which you may read in his *First Lines*, to disprove it. He held gout to be an affection of the nervous system. I shall not trouble you by detailing his argument, for I consider it an utter failure. I am satisfied that the ancient doctrine, which asserts the *humoral* origin of the disease, is the true one. “Morbific matter” (it may well be called a *poison*) is generated, or detained, under certain circumstances, within the body, and silently collects in the blood; until, after obscure threats, perhaps, and prelusive mutterings, it explodes in the foot; and then the bodily economy, like the atmosphere after a thunder-storm, is, for a while unusually pure and tranquil. To some such conclusion as this the result of all modern research seems clearly and unfailingly to tend. Sir Henry Holland, for example, in his thoughtful and thought-exciting volume, recently published, expresses his belief in “*a materies morbi*, which, whatever its nature, is capable of accumulation in the system, of change of place within the body, and of removal from it.” In this, and in several other propositions relative to gout, enunciated in distinct terms by this learned writer, I fully concur. Some speculations still more lately put forth by Dr. William Budd in a communication to the Medical and Chirurgical Society, throw a strong light upon this perplexed subject; and bring the phenomena, not only of gout, but also of many other important complaints, within the operation of one general, comprehensive, and intelligible law. I shall take leave to refer, in a very cursory manner, to some of Dr. Budd's positions.

I need not remind you of the various ways in which extraneous matters find entrance into the blood. Poisons, under their proper shape and name; medicines, which misapplied become poisons; our natural food and drink, which the folly of man

converts into poison; the products or dregs of the secondary assimilative process; these are common sources of impurities, more or less hurtful, which mix and circulate with the vital fluid. Some of these extraneous matters escape harmlessly by one or more of the waste-pipes and excretories of the body. Some are entangled in its solids: but not indiscriminately; for different substances have their special or their favourite resting-places. All this is well known to persons conversant with toxicological researches.

Now this doctrine, of the elective affinity between certain tissues or parts of the body, and certain morbid principles conveyed to them by the blood, is applied by Dr. Budd to elucidate the very curious fact of the symmetrical local manifestations of many disorders; which disorders are themselves so far general that they derive their origin from the circulating fluids. This symmetry he finds the most exact in chronic constitutional complaints, wherein the local morbid changes are effected in a manner which approximate closely to the processes of healthy nutrition. He shows good reason for believing (what, if the whole theory be true, we should expect) that the same symmetrical phenomena are modified by the *amount* of the poison collected in the system. If there be a certain quantity only, it may settle in some favourite or congenial spot, on one side of the body. If there be more than enough to saturate that part, it goes next to the corresponding spot upon the opposite side; or, perhaps, to an analogous part of the other limb of the same side. If there be more still of the poisonous material, it flies to, and occupies, other parts also. He further shows that the elective affinity is more exclusive, and the bond of union stronger, in respect of some morbid principles, than of others: and in proportion as the affinity is weak, so is the local manifestation of the disease apt to shift, by metastasis, from place to place. When the matter which has thus entered, or combined with, a certain tissue or organ, is anyhow loosened and released from that union, or repelled from the part, it is again set afloat in the blood, to "break out" elsewhere; to tease various organs, perhaps, or to derange the whole economy. The alternation so often to be noticed between certain cutaneous eruptions and internal disorders of function, is a striking and familiar example of this. The eruption afforded presumptive evidence of the detention of some peculiar morbid principle in that part; and the internal affection which succeeds the disappearance of the eruption, denotes that the morbid principle has re-entered the blood. Some of these peccant or poisonous matters fix permanently in the affected spot or spots; and some of them may even be recovered in substance from the dead tissue by chemical means: the poison of lead, for example, from the symmetrically palsied muscles. Others appear to be expended gradually in the part, and so eliminated from the system. Dr. Budd observes, that the regular arrangement of these local tokens, whether they be outward or internal, is disturbed by the presence of fever. Probably the febrile tumult may itself be owing to the quantity of the noxious matter in circulation within the body. He states, also, that, *cæteris paribus*, this morbid matter is most apt to pounce, in the first instance, upon parts which have been previously hurt, or which are mechanically irritated at the time. For which reason a part that has once been affected by it is more likely than other parts to suffer again.

Now, see how thoroughly the ascertained phenomena of gout accord with this theory. Certain habits of life produce fulness, and richness, and impurity of blood; the same habits which breed the lithic acid diathesis. We may even conjecture this acid, or some of its compounds, to be the actual *materies morbi*.¹ Lithates are poured forth with the urine, and sometimes deposited in vast masses around and within the gouty joints. At first, after obscurer intimations of the presence of the poison in the system, it thunders in the foot; and there, perhaps, is all discharged and spent. The chemist Berthollet found that the skin of a part affected with gouty

¹ This conjecture, or rather this inference from the fact stated in the next sentence, has been verified, within the present year (1848) by Dr. Garrod, who succeeds with ease in demonstrating the presence of urate of soda in excess, in the blood of gouty patients.

The same able chemist detects also urate of soda, and urea, in *minute quantities*, in healthy blood. It seems probable that various blood diseases result from different kinds or degrees of imperfection in the eliminating powers of the kidney. Thus perhaps in gout, the uric acid is but scantily excreted — the urea being separated in its natural proportion: while in some cases of "Bright's disease" the reverse of this may occur; the urea escaping with difficulty, and the uric acid coming away with the urine in its ordinary and proper quantity.

inflammation communicated instantly to litmus paper a deep red colour: a large quantity of acid was evidently passing off by exhalation from the inflamed surface. If the poison be too copious to find sufficient vent in one joint, it attacks another, or more than one other. “Quandoque etiam primis morbi diebus, cum materia peccans adeo exuberat ut ei capiendæ pes unus impar sit, utrosque simul pari vehementiâ fatigat: sed ut plurimum pedes successivè, uti diximus, adgreditur.” These are Sydenham’s words. A chain of repeated paroxysms at length purifies the blood: “donec tandem materiâ peccante prorsus absumtâ, æger pristinam obtinuerit sanitatem.” The descent of the disorder upon a particular joint is often determined by a recent blow or sprain, or by the chronic weakness consequent upon an ancient hurt. If the inflammation, after thus settling, be repelled from the foot, the poison, being driven again into the blood, may light upon some vital organ, and place the patient’s life in immediate jeopardy. The late Dr. Parry, of Bath, had at one time under his care two patients who had attempted to cut short, or to ease a paroxysm of gout, by plunging the affected foot into cold water. This gave instant relief to the pain, and in both instances the inflammation presently abated; but in both, also, *hemiplegia* occurred a few hours afterwards.

If these views respecting the pathology of gout be true, it can scarcely be doubted that they are applicable, *mutatis mutandis*, to the cognate disorder—acute rheumatism. Dr. Prout, indeed, considered *lactic* acid to have the same relation to rheumatism which *lithic* acid has to gout. Some results of a singularly interesting experimental inquiry which Dr. Richardson is at the present time pursuing, fall in with, and seem to support, this notion. Into the peritoneal cavity of a healthy cat he introduced a solution of lactic acid in water. In two hours the action of the cat’s heart became irregular. The next morning the animal was found dead. There was no peritoneal inflammation; but marked endocarditis of the left chambers of the heart. The mitral valve was inflamed and thickened, and covered on its free borders with firm fibrinous deposits. The whole inner surface of the ventricle was highly vascular.

A dog, on which a similar experiment was tried, died in two days. Unequivocal evidence of endocarditis was disclosed upon examination of the heart. The tricuspid valve was swollen to twice its ordinary size. The aortic valves, inflamed and enlarged, presented fibrinous beads along their edges: and the entire endocardial surface was red. The pericardium was simply dry. There was no affection of the joints.

The prognosis of gout may be gathered, without much further suggestion on my part, from what has already been said. The inflammation which befalls the joints has no worse *event* than the thickening, or, perhaps, the chalk-like deposit, which it produces; so that *gout in the extremities* is not a mortal disease. But as it is not always confined to the extremities, the life of a gouty person is justly held to be insecure. “La goutte articulaire (says some French author) est celle dont on est *malade*; et la goutte interne est celle dont on *meurt*.” You will find that all insurance companies exact, *cæteris paribus*, a larger premium from those who have had the gout. When it proves fatal, it is by translation of the disease, or rather of the gouty virus, to some vital part; to the stomach, the heart, the lungs, the brain.

As the early visits of gout are generally followed by a striking change for the better in the health and feelings of the patient, it is not to be wondered at that the disease, in its genuine and decided form, should have sometimes been wished for, and even courted. It is commonly thought that a fit of the gout clears the system of all other disorders. It does, indeed, clear it, for the time, of those disorders which resulted from the poison of gout. But this fact has led to great practical mistakes. First, to the error of looking on inertly, and doing nothing to remedy the ailments which are supposed (often very wrongly) to depend upon lurking gout, and to require a fit of the gout for their cure; and, secondly, to the more dangerous experiment of endeavouring to force on such a fit by excess and intemperance. Men forget, or do not know, that the enemy thus reinforced, instead of evacuating the fortress by its outposts, may retreat triumphant into the citadel. To drop metaphor, such a course of living may, indeed, determine an attack of the disease in the extremities, but it involves the fearful peril of some fatal internal seizure. Besides, the benefits expected from external gout belong to its earlier returns alone. The more numerous the fits, the faster does the general health break, and the more stub-

bornly do the associated symptoms cling to the patient: and many persons linger on, martyrs (as they say) to the disease, long after they have ceased to be fit for any of the business of life, or capable of any of its pleasures. Nevertheless, as Heberden observes, "people are neither ashamed nor afraid of it; but solace themselves with the hope that they shall one day have the gout; or, if they have already suffered it, impute all their other ills, not to having had too much of that disease, but to wanting more. The gout, far from being blamed as the cause, is looked up to as the expected deliverer from these evils."

And this mistaken ambition is heightened, no doubt, by the notion, still more absurd and ridiculous, yet very generally prevalent, that it is a *creditable* thing to have the gout: a notion which evidently originated in the fact of its being peculiarly incidental to the wealthy and the great, to men of cultivated minds, and intellectual distinction. Nothing can show more strongly the power of fashion than this desire to be thought to possess, not only the tone and manners of the higher orders of society, not their follies merely and pleasant vices, but their very pains and aches, their bodily imperfections and infirmities. All this is more than sufficiently ludicrous and lamentable: but so it is. Even the philosophic Sydenham consoles himself, under his sufferings from gout, with the reflection that it destroys more rich men than poor — more wise men than fools. "At vero (quod mihi aliisque licet, tam fortunæ quam ingenii dotibus mediocriter instructis, hoc morbo laborantibus solatio esse possit) ita vixerunt atque ita tandem mortem obierunt magni Reges, Dynastæ, exercituum classiarum Duces, Philosophi, alique his similes haud pauci. Verbo dicam, articularis hicce morbus (quod vix de quovis alio adfirmaveris) divites plures interemit quam pauperes, plures sapientes quam fatuos."

The treatment of a gouty patient naturally divides itself into that which is proper during the paroxysm, and that which is proper during the intervals between the paroxysms.

It was maintained by the great physician whose words I have just been quoting, that all artificial evacuations during a fit of the gout are useless or hurtful. He therefore discountenanced blood-letting, purging, and the use of diaphoretic medicines. It was nature's prerogative, he said, to exterminate the peccant matter in her own way; namely, by depositing it in the joints, whence it might be dispersed by insensible transpiration. Evacuant remedies had no other effect than that of recalling into the blood this peccant matter, which nature had already thrust forth to the extremities of the body; whereby it happened that the virus, which should have been eliminated through the joints, fell upon some of the viscera; and so the patient who was in no danger before, became in peril of his life. I mention all this to show you how entirely identical was Sydenham's theory of the gout with that which is now rapidly regaining its lost ground in this country, and which I firmly believe to be the true one. After his time, and upon his authority, the treatment of gout lapsed into an inert expectancy. Even Cullen came to the conclusion that the best thing to be done is commit the sick man to "patience and flannel alone." Here and there, indeed, an advocate of more active measures sprang up. Dr. Rush thought that venæsection was always safe, and generally serviceable: and some persons, following the bad example of the illustrious Harvey, were for extinguishing the inflammation by immersing the affected joint in cold water. Heberden, however, had clearer and juster views upon the subject. He perceived that one reason why physicians did nothing to check the paroxysm was, that they did not know what would check it. He agreed with Cullen in thinking "that no medicine for curing the gout had yet been found;" but he did not partake of his belief in "the impossibility of a cure by medicines."

"The itch (he observes) is supposed to be wholesome in some countries, where it is endemical; and an ague has been considered as a minister of health, whose presence and stay ought by all means to be courted. These opinions are now pretty generally exploded in England; and I hope the time will come when a specific for the gout, as certain as those which have been discovered for these two disorders, will ascertain the equal safety and advantage of immediately stopping its career, and preventing its return."

That time has come: for the colchicum, judiciously employed, may fairly be accounted a specific for the gouty paroxysm. And it is remarkable how long this truth has been seen, though not distinctly or steadily. The hermodactyl of the

ancients is the modern colchicum, and was in high estimation among them for its efficacy in the same forms of disease as are benefited by the colchicum now. It bore, with some, the name of *anima articularum*, the soul of the joints, because (as Quincey states) it prevented "the lodgment of such gritty matter as occasions the gout and arthritic complaints." And I think there can be no doubt that the active principle of the quack medicine so much in vogue for the cure of gout some years ago — I mean the *eau médicinale* — either was the same with that of the meadow-saffron, or was derived from the same family of plants which Decandolle has associated together under the title of "Colchicaceæ."

This drug has certainly the property of easing, in an almost magical manner, the pain of gout. How it operates is not so clear. It is apt to produce nausea, faintness, and diarrhœa; but its curative influence is not conditional upon the occurrence of these symptoms. Sometimes the rapid disappearance of the gouty inflammation is its only perceptible effect. The patient may be in helpless agony, with a tumified red joint, to-day; and walking about, quite well, to-morrow. The colchicum is therefore plainly an anodyne. It also sensibly modifies the condition of the urine, rendering it less acid, and even alkaline; and increasing its quantity. These effects are consequent, I presume, upon changes in the blood wrought by this substance, which thus, and there, proves somehow an antidote to the poison of gout.

There are, as you are aware, various preparations of colchicum in use: the wine of the bulb; the wine of the seeds; the vinegar of colchicum; the acetous extract, made by evaporating that vinegar; the inspissated juice of the plant itself. These are all of them active and valuable medicines; and I should pretend to more knowledge than I possess, if I undertook to tell you which of them is the best.

The mode of administering the remedy, in a regular fit of the gout, is simple enough. For example, you may give forty or sixty minims of the *vinum colchici*, in a saline draught, at bed-time; and half a drachm more, in a warm black dose, the next morning; and you may repeat this sequence if the gout continue. Some persons give twenty minims every six hours, with a drachm of Epsom salts, and a drachm of syrup of poppies in the draught, till the symptoms yield; but I prefer the other plan. In this way the pain is usually calmed, and the swelling reduced in a few days; or even, as if by a charm, in a few hours.

But you must not be satisfied with thus quelling the pain and inflammation. A strong prejudice at one time existed, and still exists among some practitioners, against the colchicum. It was said that it had indeed the power of cutting short the paroxysms, but that it cut short the patient's life also: that they who trusted to it for getting rid of the gout, very seldom lived more than two or three years afterwards. How far this was true I cannot tell; but even admitting it to be true, it was not, I conceive, so much the fault of the medicine as of the patient, or of the physician who did not properly admonish the patient. Men were very glad to get rid of their gout on such easy terms; and they will sometimes say to us now: "I have, as you see, got the gout. This is Monday. I must be in the House of Commons, or attend such and such a meeting, or be at the head of my regiment, on Wednesday: and I expect that you will enable me to do so." Or even sometimes the reason may be that they are engaged to some good dinner two or three days afterwards. Now if patients are content, and are suffered to be content, with expelling the gout from their toe, without observing abstinence more than a day or two, and without any depletion or further medication at the time, we can easily perceive the probability of their being soon attacked by some formidable internal complaint. I apprehend that the proper way to eradicate the lurking residue of the mischief is to continue to give small doses of the colchicum; five minims of the wine, for instance, two or three times a day, for a while. Moreover, purgatives must be employed, if that remedy do not prove aperient. Not violent purgatives, however, which, by weakening the patient, seem to strengthen the power of the gouty virus. With mild cathartics, moderate doses of mercury will generally be advisable, to correct the subsisting disorder of the hepatic functions; and the patient must adopt and pursue abstinent, or at any rate strictly temperate habits, in respect to meat and wine.

And as I think that the dregs, if I may so speak, left behind it by a gouty paroxysm, may be dispersed by the continued use of what, in the usual acceptation of the word, I may call *alterative* doses of colchicum (doses, that is, which produce the desired

purpose gradually, and by insensible operation) so I think it probable that many a fit of the gout might be averted, if the remedy were given in the same way upon the first occurrence of the ordinary premonitory troubles. Many of those troubles never appear to reach the crisis of a fit. There are headaches, attacks of asthma, derangements of the digestive organs, which, occurring in a gouty person, are presumed to be fainter intimations of the presence of the gouty poison in the blood; and if such symptoms yield (as unquestionably they often do) to colchicum, the presumption draws near to proof. Sir H. Holland has well remarked that the meadow-saffron, by its curative effects, may bring sundry maladies, hitherto thought anomalous, under the same law of morbid *gouty* action; just as the Peruvian bark has reduced many complaints, that were previously vague in their nature, within the same category of *aguish* distempers. The same author conjectures that as hypochondriasis is certainly often symptomatic of the gouty poison in the male, so may sometimes the kindred disease, hysteria, be in the female.

Strange stories are recorded—strange, but I believe true—of instantaneous cures of the gout by strong mental emotion; by sudden terror, by violent wrath. Dr. Rush relates an instance of this. An old man who for several years had suffered an annual attack of gout, was lying in one of these paroxysms, when his son, by some accident, drove the shaft of a wagon through the window of his room, with vast noise, and a great smashing and destruction of glass. The old man leaped out of bed, forgetting his crutches; and his wife on entering the apartment, was surprised to see him walking up and down, and exclaiming angrily against the author of the mischief. The late Professor Gregory, of Edinburgh, was in the habit of mentioning another example to the same effect, authenticated to him by a naval surgeon. It occurred in the person of an officer who was freed from an attack of gout, when at sea, by an alarm of fire. Southey again, in his autobiography, speaking of a Mr. Bradford, says, “By that time he had become a victim to the gout. An odd incident happened to him during one of his severe fits, at a time when no persuasions could have induced him to put his feet to the ground, or to believe it possible that he could walk. He was sitting with his legs up, in the full costume of that respectable and orthodox disease, when the ceiling being somewhat old, part of it gave way, and down came a fine nest of rats, old and young together, plump upon him. He had what is called an antipathy to these creatures, and forgetting the gout in the horror which their visitation excited, sprang from his easy chair, and fairly ran down stairs.” Whether this influence of certain states of the mind be rightly alleged or not, it is clear that we can never hope to make any practical use of such a remedy. Indeed, a fit of the gout has been sometimes *brought on* by a mental shock.

The treatment of a gouty patient in the intervals between his attacks of gout, whether regular or irregular, must be chiefly regimenal. The instances are not few of men of good sense, and masters of themselves, who, being warned by one visitation of the gout, have thenceforward resolutely abstained from rich living, and from wine and strong drinks of all kinds, and who have been rewarded for their prudence and self-denial by complete immunity from any return of the disease; or upon whom, at any rate, its future assaults have been few and feeble. On the other hand, many who are liable to gout are taught by sharp experience that a single debauch, a casual glass or two of champagne, even an unusual indulgence in the use of animal food, may suffice to bring their enemy suddenly upon them. I am sure it is worth any *young* man's while, who has had the gout, to become a teetotaler. But the case is different with the *old*, and with those whose health has been broken by the inveterate disease. They must be allowed a certain quantity of their accustomed good cheer, or they become an easier prey to the disease. In such cases you must trim, as well as you can, between opposite dangers; between the Scylla of excess, and the Charybdis of debility.

It is the same with respect to exercise. The young and the hearty can scarcely take too much: the old and the dilapidated, by one act of over-exertion, may incur the penalty of an attack. Although I can do little more than point out general principles for your guidance, I may remark, in reference to exercise, that it should never be *violent*, lest it excite a paroxysm by straining any part, or by causing great fatigue: that it should be *habitual*, daily—not used by fits and starts, and interrupted by long periods of indolence or inaction: and that it should be *active* muscular exercise, as

distinguished from passive exercise or gestation. No mode of exercise is so good as that of walking; and with this may be agreeably and beneficially conjoined riding on horseback.

Early and regular hours are also of much importance; and the avoidance of severe mental application. Sydenham relates that one of the most atrocious attacks of gout he ever underwent was induced by intense thought and study, in the composition of his medical works.

The regimen which I have been recommending may require some power of self-control: yet in reality it implies no severity of mortification. It is perfectly compatible with life's best enjoyments: but to be effectual it must be adopted early, as soon as the disease threatens; and steadily persevered in. Gouty persons, however, do not like these restraints. They are ready to believe that an attack of gout will do them good; or if they are disabused of that error, they are desirous that some medicine may be found which will avert the disease, without their being obliged to forego their accustomed indulgences. "To gratify this desire (says Cullen) physicians have proposed, and to take advantage of it empiries have feigned, many remedies." One of these was the famous Portland powder, of which Heberden remarks: "Unum est ex multis quæ vocantur remediis specificis, quorum ortum, et splendorem, et oecusum vidi." It consisted chiefly of bitters and aromatics, and had descended, with some slight variations in its composition, from the times of Galen. Another preventive has recently been praised by Dr. Graves, of Dublin, as being highly serviceable, although (what is a suspicious circumstance) it had, like the Portland powder, fallen out of fashion. These are its ingredients:—Two ounces of orange peel, an ounce of powdered rhubarb, and two ounces of the *pulvis aloës cum canellâ* of the Dublin Pharmacopœia, steeped for a week in a quart of brandy. A table-spoonful of the strained effusion is to be taken, mixed with two or three spoonfuls of water, night and morning. Sir Henry Hallford recommends what I think a better form of prophylactic remedy; viz. a few grains of rhubarb, with double the quantity of magnesia, every day: or some light bitter infusion, with tincture of rhubarb, and about fifteen grains of the bicarbonate of potass.

Now what has been observed respecting preventive remedies of this kind is, not so much that they are inefficacious, as that, *when exclusively trusted to*, they are unsafe. I believe that they are often useful by improving the digestive process; but they are dangerous substitutes for a course of temperance and exercise.

When gout attacks the stomach, either by retrocession or primarily, it often proves rapidly fatal. The gastric affection is not, in general, inflammatory: so we judge, at least, from the *juvantia*. The attack, which consists of violent pain, and a sense of weight or of constriction in the epigastrium, with sickness, vomiting, and a disposition to faint, is often relieved by the employment of stimulants. But such remedies would be likely to aggravate inflammation. It will always be well when symptoms like these occur, to inquire whether any indigestible food has been lately taken: for *gout* (so called) *in the stomach* has sometimes turned out, under the test of an emetic, to have been nothing more than *pork in the stomach*. In the true gouty seizure, antacids will frequently remove the pain; magnesia, in full doses, with rhubarb. If this do not succeed, opium may be resorted to; and if it should be vomited, opiate enemata may be injected. Dr. Heberden thought that opium, and hot spices, were more efficacious and less inconvenient, in these cases, than wine and spirits; but when they fail, a glass of brandy will often allay the pain completely. The mustard poultice, or the turpentine stupe, applied over the epigastrium, has been followed by strikingly good effects. And it is in these emergencies; contingent upon retrocedent or misplaced gout, that we are justified in the endeavour to induce gout in the extremities; not however by internal stimuli, but by enveloping the feet in a mustard poultice, and so enticing or provoking the foe to quit his hold of the interior, and to appear in the outposts. And this expedient should be practised, whatever may be the internal organ upon which the gouty disorder has settled.

Sometimes, but much less commonly, actual gastritis does seem to ensue; and therefore all these cases are anxious and alarming cases. I do not know how the inflammatory affection can be discriminated from the non-inflammatory, unless it be by the occurrence of *tenderness* with the pain, and of fever. You must treat such

cases as you would treat an ordinary case of gastritis, taking no further heed of the gout, except by the application of stimulating cataplasms to the feet.

This concludes what I proposed to say respecting gout and rheumatism : diseases of which the local seat is not exactly external, nor yet do they belong strictly to the interior of the body, except in their accidental complications. They form a link of connexion between the internal and external disorders which fall to the care of the physician ; and I proceed, in the next and last place, to speak of those complaints which either concern the integuments alone ; or which, at any rate, are attended with some notable affection of the skin.

Under the general head of *cutaneous* diseases, are included maladies of very different kinds, and of very different degrees of importance. Some are attended with fever, and run a definite course, and are often dangerous to life. Others are chronic, irregular in their progress, troublesome perhaps, and obstinate, and disfiguring, yet implying no peril to the existence of the patient. Some again are contagious, while many are not so. But before I enter upon any further account of these diseases, I wish to make you acquainted with the names by which the various morbid appearances presented by the skin have been known, since the time of Dr. Willan.

That author—whose works have been augmented by Dr. Bateman, so that perhaps I ought to say *those* authors—divides cutaneous diseases into eight orders, distinguished from each other solely by the appearances upon the skin. I shall omit the last of these orders, the order of *maculæ*, such as freckles and congenital spots and discolorations, because in fact these are not diseases at all.

The first, then, of the appearances described by Dr. Willan are *papulæ* ; pimples. These are little elevations of the cuticle, of a red colour, and solid ; not containing, I mean, any fluid. They are of uncertain duration, and often terminate in scurf. They are supposed to denote inflammation of the papillæ of the skin. If you wish for an example of a papular eruption, look at that of small-pox, at its very earliest outbreak.

The second are *squamæ* ; scales. These are small, hard, thickened, opaque, whitish patches of unhealthy cuticle. The subjacent surface is red. They are well seen in lepra and psoriasis ; and are very common in syphilitic eruptions.

The third are *exanthemata* ; rashes. They consist of superficial red patches on the skin, variously figured, and irregularly diffused, and of all sizes. We have examples of them in some of the most important febrile cutaneous diseases ; scarlet fever, measles, and others. Most commonly they are followed by a peeling off, or desquamation as it is called, of the cuticle.

It is a pity that some other technical denomination was not chosen to express these rashes ; for the term *exanthemata* has long been familiar to the profession as the title of an order of diseases in Cullen's Nosology.

The fourth are *bullæ* ; blebs, miniature blisters. Portions of cuticle, of considerable magnitude, are detached from the subjacent skin, by the interposition of a thin transparent liquid ; with inflammation beneath them. Such occur in crysipelas sometimes, and in pemphigus.

The fifth are *pustulæ* ; pustules. Circumscribed elevations of the cuticle, containing pus, and having red inflamed bases. We have instances of these in common boils ; and in the eruption of small-pox when at its height and maturity. They end in crusts, or scabs.

The sixth are *vesiculæ* ; vesicles. Small elevations of the cuticle, covering a fluid which is generally clear and colourless at first, but becomes afterwards whitish and opaque, or pearly. These are exemplified in the eruption of cow-pox, and in the chicken-pox. You will observe that these vesiculæ differ very little, except in size, from the bullæ or blebs. They often terminate in small scabs.

The seventh are *tubercula* ; tubercles. This also is an unlucky appellation, since the word tubercle is almost appropriated, in the present day, to the serofulous deposits which infest the lungs and other parts of the body in pulmonary phthisis. However, these cutaneous tubercles are small, hard, superficial tumours, circumscribed and permanent ; or if they suppurate at all, the suppuration in them is partial. Sometimes they slowly ulcerate at the summit. The imperfectly suppurating pustules of the modified small-pox, and certain red spots which are apt to haunt the face, particularly of young persons, furnish examples.

Now it is very convenient, for the purpose of distinguishing different diseases, and of describing them, to know these outward marks when you see them, and to use these names. But they form a very unfit basis for the *classification* of diseases. Maladies may usefully be classed according to their causes; according to their intimate nature; according to the general plan of treatment they may require. But the superficial markings of disease have no definite relation to any of these heads. Besides, a complaint, which is popular to-day may be vesicular to-morrow, and pustular next Saturday. Yet the classification most commonly followed in this country, and in France, is that of Willan and Bateman. Here we find collected under one and the same division, maladies which nature has stamped with broad and obvious marks of distinction; the febrile with the non-febrile; contagious complaints with those which have not that property; ailments that are local and trivial, with diseases of grave import, and deeply-rooted in the system at large. And, on the other hand, distempers which nature has plainly brought together, and connected by striking analogies and resemblances, this methodical arrangement puts widely asunder. I point out, without professing to remedy, these imperfections. I cannot even undertake to give you any full or systematic account of the many disorders comprised in this classification. There is, however, one group, so remarkable, so important, and so highly interesting, that I shall consider it as much in detail as I can. I allude to the group which Cullen comprehends under the title *exanthemata*. With this exception, the advancing year warns me that I must contract what I have to say respecting diseases of the skin within very narrow limits.

LECTURE LXXXIII.

Exanthemata. They are contagious; sometimes epidemic. Period of the eruption; period of incubation; Theory of contagious Febrile Diseases. Continued Fevers.

OF the numerous complaints which are ranked among the diseases of the skin, some, I observed in my last lecture, are attended with fever, and some are not.

Among the former there is a highly interesting group, distinguished by other and more important characters than the mere presence of fever, or peculiar marks upon the skin; characters that enabled Cullen to collect these diseases into a separate order, to which he gave the name of *exanthemata*. This is his description of them. “*Morbi contagiosi, semel tantum in decursu vitæ aliquem afficientes; eum febre incipientes; definito tempore apparent phlogoses, sæpe plures, exiguæ, per eum sparsæ.*” Contagious diseases; attacking a person once only in his life; beginning with fever. At a definite period small inflammations appear, often numerous, scattered over the skin.—These you will allow, are very remarkable characters. They are not all strictly and universally true, perhaps, of all the forms of disease which I propose to bring now under your notice; but they apply with more or less exactness to the several species of continued fever, to the plague, to small-pox, chicken-pox, measles, scarlet fever, and erysipelas.

Whooping-cough, and the mumps, might be placed in the same catalogue, although in them there is no specific eruption on the skin: but I have already spoken of these two disorders.

Before I take up the consideration of any one of these diseases in particular, I shall premise a brief survey of certain circumstances that are more or less common to them all. The preliminary examination of the *exanthemata* as a class, will give you, I trust, clearer ideas respecting each of them: at any rate it will enable me to dispense with much needless repetition afterwards, and so to save both your time and my own; a matter of some consequence at this advanced period of the session.

In the first place, then, the diseases comprehended in this group are *contagious*

diseases. You will hear persons disputing about the *term* contagion; but such disputes can only arise from the want of a distinct definition of the sense in which it is employed. I understand a disorder to be contagious, when it is in any way *communicable* from one person to another. Some would restrict the word contagion to the cases in which there must be absolute *contact* of the healthy body with the sick body, or with its visible offscourings. When the disease can be conveyed through the medium of the atmosphere, or by means of other intermediate substances called fomites, they would call it *infectious*. And there is no objection to such a distinction, provided it is understood by the reader, or hearer, as well as by the writer or speaker. But since in all cases the disease is conveyed to the person of the recipient by particles of matter proceeding from the person of the sick, and since it seems very unimportant whether those particles are in a solid or in a gaseous form, whether they are imparted by direct contact of the two human bodies, or by being wafted through the air, or carried upon articles of clothing, I shall include both and all these modes of communication under the single term contagion. This, in fact, is what is done in common discourse: all disorders that are "catching," I shall take leave to consider *contagious*.

In this sense I believe that all the diseases just now enumerated *are* contagious; some, no doubt, much more strongly and distinctly so than others. Some of them, indeed, are undeniably contagious. For example, we are privy to, and sometimes willing agents in, the communication of small-pox from one individual to another. There are others concerning the contagious nature of which medical opinion is less settled and unanimous. Many persons deny that continued fevers are communicable from person to person. The evidence from which I conclude that they are so, I will lay before you when I have described those disorders. Even they who admit that they are contagious, are of opinion, many of them, that they sometimes break out spontaneously, without the intervention of any specific virus. No one questions, I fancy, the contagious properties of measles; or of scarlet fever. Whether the plague, and whether erysipelas, be always or ever so produced, has been thought more doubtful. There is every reason for believing that the small-pox, at least, has now no other source than contagion. How it first arose it may be difficult to conjecture; but it is never known to originate spontaneously now-a-days.

Small-pox may in truth be regarded as the *παράδειγμα*, or type, of this group of diseases. I shall therefore take, by anticipation, some well-ascertained facts in its history, for the sake of illustrating the general subject. It is a malady which could scarcely be mistaken for any other; and of which the horrible aspect and fatal tendency are so strongly marked, that its appearance has always been watched with affright by mankind in general, and with intense interest by the philosophic physician.

In the acme of this disease, when it is severe, the whole surface of the body is covered with innumerable little pustules. A minute portion of the matter contained in any one of these pustules, just so much as may suffice to moisten the point of a lancet, is inserted, we will suppose, beneath the cuticle of a healthy man, who has not been near the sick man. What follows this engrafting? Nothing, apparently, for several days: but then febrile symptoms burst forth: and by and by a crop of papule appear sprinkled over the skin; and these gradually ripen into pustules precisely resembling that from which the engrafted drop was taken.

The very same phenomena ensue, when a healthy man enters the chamber of a small-pox patient, and breathes, for a certain time, an atmosphere tainted with the emanations from his body.

The points to be noticed here are — 1, the manifest introduction of the virus into the system: 2, its dormaney for a while; in other words, the occurrence of a period of incubation: 3, the breaking out, at length, of a disease identical in its symptoms and in its character with that of the first patient: and 4 (most surprising of all), the enormous increase and multiplication of the poisonous matter.

I say the *history* of small-pox leads to the settled belief that this disorder, of which few persons are not readily susceptible, never occurs, except from contagion. It appears to have been unknown in Europe till the beginning of the eighth century. No mention of any such malady is to be found in the Greek or Roman authors of antiquity. Now whatever may have been the deficiencies of the ancient physicians, they were excellent observers, and capital describers of disease: and it seems to me

scarcely possible that a disorder so diffusive, and marked by characters so definite and conspicuous, should have escaped their notice, or have been *obscurely* portrayed (if known) in their writings.

On the other hand, Mr. Moore, in his learned and interesting *History of Small-pox*, has shown that it prevailed in China and Hindostan from a very early period; even more than 1000 years before the time of our Saviour. That it did not sooner extend westward into Persia, and thence into Greece, may be attributed partly to the horror which the complaint everywhere inspired, and the attempts that were consequently made to check its progress by prohibiting all communication with the sick, partly to the limited intercourse which then took place among the eastern nations, but principally to the peculiar situation of the regions through which the infection was diffused; separated as they were from the rest of the world by immense deserts and by the ocean.

The disease is said to have broken out in *Arabia* at the siege of Mecca, in the year in which Mahomet was born; *i. e.*, in the sixth century. It was widely propagated by his wars, and by those of the Arabs afterwards; and, as I said before, it is generally believed to have first found entrance into Europe at the time of the overthrow of the Gothic monarchy in Spain by the Moors; when to avenge the well-known outrage upon his daughter "Count Julian called the invaders." Whensoever and wheresoever it came, it spread with fearful rapidity and havoc.

What I wish you to remark is this: that while almost all men are prone to take the disorder, large portions of the world have remained for centuries entirely exempt from it, until at length it was imported; and that then it infallibly diffused and established itself in those parts.

Of the more modern history of the disease our knowledge is more precise and sure. It tends uniformly to the same conclusion.

There was no small-pox in the New World before its discovery by Columbus in 1492. In 1517 the disease was imported into St. Domingo. Three years later, in one of the Spanish expeditions from Cuba to Mexico, a negro covered with the pustules of small-pox was landed on the Mexican coast. From him the disease spread with such desolation, that within a very short time, according to Robertson, three millions and a half of people were destroyed in that kingdom alone. Small-pox was introduced into Iceland in 1707, when 16,000 persons were carried off by its ravages; more than a fourth part of the whole population of the island. It reached Greenland still later, appearing there for the first time in 1733, and spreading so fatally as almost to depopulate the country.

Evidence to the same effect is furnished by the results of vaccination in some countries. Take one instance. Vaccination was adopted in Denmark in 1801, and made compulsory in 1810. From that time small-pox disappeared altogether, for fifteen years; whereas during the twelve years preceding the introduction of the preventive disease, upwards of 3000 persons died of the small-pox in Copenhagen alone.

Now it is a very instructive fact respecting this disease, thus rankly contagious, and arising from no other source than contagion, that when it is epidemic in any place, many instances of it occur which we can by no means trace to contagion. Dr. Gregory tells us that of the numerous cases received into the Small-pox Hospital (to which he had long been physician) not one in twenty is capable of being referred to any known source of infection; the disease being ascribed by the patient to cold, fatigue, change of air, or some other innocent circumstance. A prisoner shut up in solitary confinement in the Penitentiary at Millbank was seized with small-pox. Surely this should warn us against inferring of analogous disorders (of continued fevers, for example) that they are necessarily not contagious, because we often fail to discover any way in which the poison could have been applied. If small-pox be produced by contagion alone, and yet the mode in which the contagious matter has been communicated eludes sometimes our closest scrutiny, then we must conclude that the same thing may happen in *other* contagious diseases, of which the contagious property may not be so strong or so obvious. Nay, the argument from analogy will lead us a step further. If once a disorder of this kind is decidedly proved to be sometimes the effect of contagion (and this I think I shall be able to prove to you of continued fevers)—we cannot help entertaining a doubt whether the disorder in question

really ever has any other cause. It is chiefly with a view to the light which they throw upon the obscurer subject of continued fever, that I am thus anticipating some points in the history of the contagious nature of small-pox.

Again, it is noticed of small-pox — and it is the same with the other diseases in this group — that the human body is not always equally susceptible of its contagious influence. Some individuals are more readily affected by it than others: and the same individual more so at one time than at another. There are even some who seem to be incapable of taking the small-pox — just as some, who are quite as much perhaps in the way of it as their neighbours, never become infected with the great pox. Mr. Cross, in his *History of a Variolous Epidemic* which occurred at Norwich in 1819, tells us that of 215 persons who had not been vaccinated, nor had the small-pox, and who were living at Norwich in the same houses with persons ill of that disease, fifteen did not become affected with it; and of these fifteen it was ascertained that ten had escaped under similar circumstances of exposure before. I mentioned, on a former occasion, the fact that a certain dog, in Paris, could not be made to take the contagion of rabies.

It is not at all uncommon for persons to resist the influence of contagion at one period, and to yield to it at another, even when the exposure has appeared to be less complete. Mr. Cross gives a striking example of this. A man, who believed that he had had the small-pox, lived for twelve years as a nurse in an establishment for the reception of persons inoculated with that disorder. At the end of that time he caught the small-pox, which proved fatal to him. Now this might have been, and probably was, as the man supposed, a *second* attack. The late Mr. Lockley told me an instance still more remarkable, as being free from that ambiguity. Nearly the first patient he ever attended, if not the very first, was an old woman, who for years had been in the habit of going from village to village as a nurse; and of nursing a great number of persons labouring under small-pox, which she had never had, and against which she (naturally enough) believed herself proof. At length she was taken ill, and died of small-pox, under Mr. Lockley's observation, at the age of eighty-four. Take one more illustration from another of these disorders. In 1845, a lady with whom I am acquainted went through an attack of measles, that disease being prevalent in the village where she was then residing. She had never had the measles previously: yet she had, long before, personally tended eleven of her twelve children, when ill of the same complaint.

In many cases we can assign no reason for these variations and differences. Age seems to have something to do with them. Infants are but little susceptible of the operation of contagions. Debility, howsoever produced, certainly augments the disposition to be affected by this, as by other causes of disease. The dose and strength of the poison must also be taken into account. As some men can drink a much larger quantity of wine (which is an alcoholic poison) than others, without being intoxicated, and are differently influenced by the same quantity at different times, so is it also with the animal poisons we are now considering; so is it, as I showed you before, with the mineral poison of mercury.

This fluctuating power to resist contagion is most conspicuous, perhaps, when viewed in reference to scarlet fever. After the very earliest periods of life, children catch infectious disorders of all kinds readily enough; more readily than in mature age. The poison of scarlet fever operates with less certainty upon adults than the poisons of small-pox, or of measles. Some medical men escape scarlet fever altogether, although brought much into contact with it by their vocation. I do not know that I ever had scarlet fever.

Another fact, well worthy of notice, is, that small-pox, which is so rankly contagious, and which has at present no other source besides contagion, has its alternate periods of slumber and of activity. This metropolis, and most of our large towns, are never entirely free from it. Scattered cases occur, here and there; and when thus thinly disseminated, the disease is said to be *sporadic*. But there are seasons in which it spreads rapidly and extensively, and assumes the form of an *epidemic* distemper. We are now living (1838) in the midst of one of these epidemics of small-pox. The same is equally true of the other complaints included in this group. Sometimes they are confined to single families; sometimes they pervade a whole district.

Hence you can never infer that any febrile disorder is not contagious, merely

because it prevails epidemically. Many epidemic diseases are not contagious. But the two properties may and do meet in the same malady. They are not to be set in opposition to each other, or regarded as incompatible properties, as they have been by some ingenious writers.

With respect to these epidemic visitations of the exanthemata, certain general facts have been ascertained, very useful and necessary to be known.

1. The strength of the contagion, and the severity and fatality of the disease, vary at different periods of an epidemic. In general the contagion is the most active, and the disorder the most fierce, at the outset of the epidemic. By degrees its violence slackens, and it ceases to spread. This is partly to be explained by the circumstance that the number of persons who are susceptible of the disease, and who have not yet been attacked, are fewer and fewer as the epidemic proceeds. The fire languishes for lack of fuel. But this does not seem to be all. The disease dies out before it has affected all those who are capable of receiving it. We might I think expect, prior to experience, that the earlier cases would usually be the severer; for the weak, who are less liable to struggle with the complaint, and those who, by peculiarity of constitution, are most susceptible of morbid influence, are likely to be the first to suffer.

2. There are great varieties also in the general character of the symptoms that occur in different epidemics of the same disorder. At one time, or in one place, inflammatory symptoms run high; in another place, or at another time, there is an early tendency to debility and sinking. One epidemic is more malign than another. And the practice varies accordingly: so that these are facts of the greatest importance. The prevailing character of the malady is attributed to what is called the *epidemic constitution of the season*. And when we have made out, by observation, what this epidemic constitution is, we have obtained a clue to the proper management of the disorder. Thus continued fever, as it has appeared in London during the last five-and-twenty years, has required and borne far less depletion than it did for the preceding twelve years or more.

You may learn from this how dangerous it is to apply indiscriminately in one epidemic the remedies that may have been found useful in another: and also how foolish and unfair it is to censure the practice employed and recommended by others, merely because it differs from that which we, in other epidemic visitations of the same disorder, have considered fitting and beneficial.

These differences in the prevalence of the disease, and in the character of its symptoms, are not to be explained by any variation in the exciting cause, which is a definite animal poison; nor can they be reasonably ascribed to any appreciable quality or agency of the weather *at the time*. They must depend upon changes that have been slowly wrought upon the human body: and those changes, constituting an acquired predisposition, are probably due to *previous* conditions of the atmosphere, which have exercised a long and gradual influence upon all the individuals of a community.

After stating, in the first clause of his definition, that the exanthemata are contagious diseases, Cullen announces, in the next place, the very curious fact, that they occur but once in a person's life. "*Semel tantum in decursu vitæ aliquem afficientes.*" In this they offer a remarkable contrast to inflammations, which having happened once, are, for that very reason, more apt to happen again.

You will take care to observe, that it is not the mere circumstance of the disease being *contagious* that makes the difference. Those disorders which shield the system against their own future recurrence are, all of them probably, contagious; but the converse does not hold. It is not true that all contagious disorders protect the constitution from their own return. Syphilis, purulent ophthalmia, the itch: these not only do not secure a patient from a repetition of the disease, but perhaps they even render him more liable to it in future.

Neither is the proposition absolutely and invariably true of any disease. Like most general rules, it admits of occasional exceptions. There is not one of the group enumerated in the beginning of this lecture, which has not been known to occur more than once in the same person. Small-pox has, in many instances, affected the same individual twice; even when the first attack had been so severe as to have engraved deep traces of its visit upon the skin. There are a few instances recorded of its *third*

occurrence. It was believed, at one time, that whenever the disease was thus repeated, it was *always*, in the first instance, severe, which, taken in conjunction with the repetition, was thought to indicate a strong natural susceptibility of the disorder. But it has since been noticed that the primary visit is sometimes unusually mild; and this fact (so powerful is the love of theory) has led to the supposition that the first attack was not sufficiently intense to affect the whole mass of blood, and to exhaust the inborn susceptibility. I believe that the two attacks have always been separated by a considerable interval of time. I have myself known two very striking instances, about which there could be no mistake, of the recurrence of measles in several children of the same parents. This proclivity to be again affected by the specific poison seems to run in families. It is less uncommon for scarlet fever to happen a second time in the same individual. No contagious disease therefore furnishes complete future protection against itself. But that this privilege belongs, as a general rule, to small-pox, to measles, and to scarlet fever, there can be no doubt: and the validity of the rule is applicable in the order in which I have here mentioned them. It applies also, though less uniformly, to the other exanthemata. A person who has suffered a well-marked attack of continued fever is far less liable than another, according to my experience, to have that same disease again. The plague is said to afford a temporary safeguard against itself. Very few persons have it twice in the same season. During one epidemic Dr. Russell found that, among 4,400 individuals who underwent the disease, only twenty-eight contracted it a second time. The singular property we are now considering is less plainly visible in erysipelas than in any other malady of the group.

The next clause in Cullen's definition asserts the supervention of the cutaneous marks, in technical language of the *eruption*, at fixed times (*definito tempore*) after the commencement of the general fever. It is clear, therefore, that the cutaneous inflammation cannot be the cause of the fever, but is itself an effect of the contagious poison. Here again we have a point of distinction between the febrile exanthemata and inflammatory fevers, or what Cullen calls the phlegmasiæ, in which the local inflammation commonly precedes the pyrexia.

In reality the circumstance to which I have just referred shows the impropriety of ranking these diseases under the head of *cutaneous* diseases. They would more rightly be called *blood* diseases. The disseminated cutaneous inflammation is a curious and an important circumstance; and it is the symptom which, in the majority of cases, is most *distinctive* of the disorder: but it is not an essential circumstance. Thus, although there are commonly distinct eruptions (quite independent of common petechiæ) in the earlier stages of typhus and of typhoid fever, a lenticular mottling, somewhat like that of measles, or a number of rose-coloured spots, yet these are often absent altogether. And the very same thing happens in other diseases of the same group—diseases which all the world considers and calls cutaneous. A febrile affection, often a fatal one, but attended with no rash, proceeds sometimes from the contagion of scarlet fever. The fever—or rather the patient—is *not* scarlet. The worst form of *cynanche maligna* is of this kind. It is just the same in measles. Authors speak of morbilli sine morbillis; of scarlatina sine scarlatinâ; and even of variolæ sine variolis. Catarrhal symptoms certainly occur sometimes in weakly children who have been fully exposed to the contagion of measles; and the complaint has proved fatal, without there having been any eruption at all. So in the plague: certain cases occur in which there are no buboes nor carbuncles, yet which undoubtedly originated from the common contagion of the prevailing epidemic.

The time at which the eruption comes out differs in the different diseases; and even in the same disease it is subject to occasional variation. The rule with respect to small-pox is, that the spots begin to be visible on the third day; that on which the sickness and fever commenced being reckoned the first. As far as I have observed, this rule is a very constant one. It has been noticed, however, that when the disease is confluent, and therefore severe, it occasionally shows itself in eruption on the second day; and when quite distinct and mild, sometimes not till the fourth.

The regular period for the outbreak of the cutaneous affection in measles is the fourth day: it scarcely ever begins sooner; but it is often later—on the fifth or the sixth day, or even later than that.

Cullen assigns the fourth day for the ordinary appearance of the rash in scarlet fever also. But in this he is decidedly wrong. Sometimes it is, I believe, perceptible on the first day; but its most general period is the second day. In severe and unfavourable cases it may be postponed till the fourth day, or longer.

The eruptions which are tolerably constant in some species of continued fever, observe less exact regularity in the time of their arrival.

The period which intervenes between the reception of the poison, and the super-vention of distinct symptoms—the period during which the virus, though doubtless at work, seems to lie dormant in the system—the period (in one word) of *incubation*, differs also in the different diseases of this group, and varies even in different cases of the same disease. Although no marked changes occur during this period, I believe that some slight deviations from the usual condition and feelings of the patient might often be observed, if they were expected and looked for.

The period of incubation in continued fevers is very uncertain. In a paper upon this curious subject, published in the ninth volume of the *Medical Gazette*, Dr. Gregory states it as his opinion, derived from much inquiry, that ten days is the *average* period. Dr. Haygarth reckoned the minimum period at seven; the maximum at seventy-two days. Sir William Burnett, in his *Account of a Contagious Fever at Chatham*, gives the history of a party of men belonging to the *St. George*, lying at Spithead, who were sent, on the 3d of January, 1811, to assist in navigating the *Dolphin* troop-ship; the crew of which were affected with typhus fever. On the 10th (seven days after exposure) fourteen of these men were sent to the Hospital-ship from the *St. George*, ill with the fever; and many subsequently, up to the 21st of January (the eighteenth from exposure); after which period no cases occurred.

The period of dormancy is more definite, yet still liable to some variation, in most of the other exanthemata. "At the Small-pox Hospital," says Dr. Gregory, "abundant evidence has been afforded that the period of incubation is usually about twelve days." It is a remarkable fact that, "when the small-pox is received into the system by inoculation, seven days only elapse between the insertion of the virus and the establishment of the fever."

Dr. Bateman puts the period of incubation in measles at "from ten to fifteen days." I have known several instances in which the date of a single short exposure was exactly ascertained, and in which the disease commenced precisely a fortnight afterwards. In scarlet fever the average period is shorter; not more than from four to six days. In the plague it is, I believe, more variable; but generally not exceeding a few days. Dr. Russell tells us that, among those inhabitants of Aleppo who shut themselves up after having been in the way of the contagion, no instance occurred of the appearance of the malady later than the ninth or tenth day.

To say that a febrile disorder is contagious, is the same thing as to say that it is produced by an *animal* poison. Now there are many poisons, very deadly poisons too, which cause diseases that are not communicable from person to person. That particular poison, the *malaria*, is of this kind.

Of the inorganic poisons some are taken into the blood and emerge again from the body, unaltered, with one or more of the ordinary secretions; chiefly with the urine. They may induce changes in the body as they pass; and if these changes be salutary, the substances so inducing them become medicaments. If the changes be destructive or injurious, they are strictly poisons.

Other of the inorganic poisonous substances do not find so ready an exit from the body. They enter into permanent chemical union with the constituent tissues of particular organs. In this way, to use the words of Liebig, they deprive the organs of the principal property which appertains to their vital condition, viz., that of suffering and of effecting transformations. If the organs of which the functions are thus destroyed, are vital organs, these poisons are fatal.

But the animal poisons, those at least with which we are now concerned, act in a totally different manner. They effect changes in the blood, whereby they are themselves abundantly multiplied or reproduced; and the eruptive disease that ensues seems to be the mode provided by nature for the escape or the expulsion of this newly-formed morbid matter from the system. This is the old-fashioned humoral pathology; founded on bold, unproven speculation: and it is most curious to see these very

doctrines, which had sunk into universal discredit and contempt, now again assuming their places, as scientific truths, upon the secure basis of organic chemistry. A wonderful specimen this of the sagacity of the older physicians—of the despised wisdom of our forefathers.

The ancients attributed various disorders to a fermentation of the animal fluids. The cause of fever, according to Hippocrates, was some morbid matter in the blood. This matter, by a process of concoction, was brought, in a certain number of days, into a state in which it was ready for expulsion from the body. It was then thrown off by hæmorrhage, by sweat, by alvine discharges; or deposited upon the surface in the form of abscess, or cutaneous eruption: and these eruptions or evacuations constituted the crisis of each fever.

The doctrine thus enunciated by the father of physic is very nearly the same with that which Liebig is teaching in the nineteenth century. This distinguished chemist ascribes the phenomena which succeed the introduction of certain animal poisons into the blood, to a process resembling fermentation. Let me try, in a few sentences, to expound to you his views on this deeply interesting subject.

You know that the brewer excites the fermentation of his *sweet-wort*, by adding to it a small quantity of *yeast*. Wort is an infusion of malt, and contains sugar and gluten, with other vegetable matters, in solution. Yeast, as I showed you in a former lecture, is a cryptogamous plant or fungus, which undergoes rapid change and development when placed in a solution of sugar. During this development, and apparently in consequence of it, alcoholic fermentation takes place; the elements of the sugar arrange themselves into new and simpler forms: namely, into alcohol and carbonic acid. If there were no gluten in the wort, this would be the whole of the process; during which the added yeast disappears.

But the presence of gluten makes a prodigious difference. The yeast increases enormously at the expense of the gluten, and mingling with the liberated carbonic acid, rises and floats upon the surface of the fermenting liquid. So that, when the process is completed, there has been produced thirty times as much yeast as was originally added to the wort.

Now this, according to Liebig, is but a type of what happens in other fluids under analogous circumstances. He maintains that (I use the words of his translator), “a substance in the act of decomposition, added to a mixed fluid in which its constituents are contained, can reproduce itself in that fluid, exactly in the same manner as new yeast is produced when yeast is added to liquids containing gluten.”

Thus the virus of small-pox (which virus is formed out of the blood) causes such a change within the blood as gives rise to the reproduction of the poison from certain constituents of that fluid: and whilst this process is going on, the natural working of the animal economy is disturbed: the person is ill. The transformation is not arrested until the whole of that ingredient in the blood which is susceptible of the decomposition has undergone the metamorphosis.

Liebig shows that similar processes may take place in mixed fluids (and therefore in the blood) without the regeneration of the added substance: just as the fermentation of a solution of sugar is effected by the addition of yeast, without any reproduction or multiplication of the yeast, if there be no gluten in the saccharine solution. In such cases, the disease, which accompanies, or results from, the transformations that occur in the blood, is not contagious: the poison is not renewed. It is thus that certain *miasms* produce disorders which are not communicable from person to person.

In order, then, that a specific animal poison should effect its own reproduction in the blood, and excite that commotion in the system which results from the formation and expulsion of the new virus, it is requisite that a certain ingredient (analogous to the gluten in the brewer's sweet-wort) should be present in the blood: and this ingredient must have a definite relation to the given poison.

If this ingredient be indispensably necessary to life, the poison, which transforms and destroys it, is inevitably a fatal poison. May not this be the *modus operandi* of the poison of hydrophobia?

Again, if this ingredient be wanting, no reproduction of the poison takes place; nor, of course, any of those symptoms which are consequent upon such reproduction. The poisonous qualities of the animal substance are not developed. It ceases to be a poison.

And this ingredient, if naturally present, is exhausted and destroyed, for a while at least, by the operation of the poison. Hence, for a while at least, the same disease cannot be again produced by the agency of that poison.

Supposing the ingredient to be one which is not essential to the composition of the blood, and to have been thus destroyed or exhausted, it may never be replaced. Or it may be replaced only after a long interval. In some persons it may never exist at all; or it may exist at certain periods only of their lives. It may even be acquired by unnatural or peculiar modes of living.

All this is possible and plausible. A certain number of peculiar substances do certainly exist in the blood of some men which are absent from the blood of others. In childhood and in youth the blood of the same individual contains variable quantities of substances, which are not to be found in it at other periods of life.

This theory of Liebig's offers, then, an intelligible explanation of the curious facts, that certain contagious disorders furnish a protection, temporary or permanent, against their own return; that they have a tolerably definite period of incubation, and run, for the most part, a determinate course; that some persons are less susceptible than others of the influence of these animal poisons, or not susceptible at all; and that the same individual may be capable of taking a contagious disease at one time, and not at another.

Mr. Simon, in his admirable *Lectures on Pathology*, which I earnestly commend to your diligent study—Mr. Simon, while he scouts the notion of any true fermentation in these cases (indeed Liebig could hardly have advanced the example of yeast in wort otherwise than analogically, just as we all speak, now-a-days, of *zymotic* diseases), adopts in full the hypothesis of some material which, pre-existing in the blood, but not being an essential part of it, combines somehow with the exciting virus from without, to cause both the febrile commotion, and, in consequence of the exhaustion of that material, the subsequent immunity from the same disorder. He even indicates the possible identity of the inbred material with certain "wastes of the tissues." "In infancy (he writes), in early age, and till puberty, there are certain waste materials which never afterwards occur: the temporary cartilages have to waste away, the thymus gland has to decay, peculiar changes referable to the sexual system have to be accomplished, and the effete products of these changes have to be eliminated from the system." He points to the fact that "the surfaces and organs most prone to affection in the diseases under consideration are those which are eliminative and defecating: those whose normal products can hardly be retained for any time within the body, much less out of it, without undergoing a fetid decomposition, which sufficiently stamps them with an excrementitious character. Bowels, skin, kidney, tonsils, are the favourite resorts of the several fever poisons, just as they are the surfaces by which naturally the organic waste of the several tissues is eliminated."

This curious subject is looked at in a different light by Mr. Paget. "*The maintenance of morbid structures* is (he says) so familiar a fact, that not only its wonder but its significance seems to be too much overlooked. What we see in scars and thickenings of parts appears to be only an example of a very large class of cases; for this exactness by which the formative process in a part maintains the change once produced by disease, offers a reasonable explanation of the fact that certain diseases usually occur only once in the same body. The poison of small-pox, or of scarlet fever being, for example, once inserted, soon by multiplication or otherwise affects the whole of the blood; alters its whole composition: the disease, in a definite form and order pursues its course; and finally the blood recovers, to all appearance, its former state. Yet it is not as it was: for now the same material, the same variegated poison, will not produce the same effect upon it; and the alteration thus made on the blood or the tissues is made once for all: for commonly, through all after life, the formative process assimilates, and never deviates from, the altered type, but reproduces materials exactly like those altered by the disease: the new ones therefore, like the old, are incapable of alteration by the same poison, and the individual is safe from the danger of infection.

"So it must be, I think, with all diseases which, as a general rule, attack the body only once. The most remarkable instance perhaps is that of the vaccine virus. Inserted once, in almost infinitely small quantity, yet, by multiplying itself, or otherwise affecting all the blood, it may alter it once for all. For, unsearchable as the

changes its effects may be; inconceivably minute as the difference must be between the blood before and the blood after vaccination; yet in some instances that difference is perpetuated; in nearly all it is long retained; by assimilation the altered model is precisely imitated, and all the blood thereafter formed is insusceptible of the action of the vaccine matter.

"But it will be said, the rule fails in every case (and they are not rare) in which a disease that usually occurs but once in the same body occurs twice or more. Nay, but these are examples of the operation of that inner yet not less certain law — that after a part has been changed by disease, it *tends* naturally to regain a perfect state. Most often the complete return is not effected: but sometimes it is, and the part at length becomes what it would have been if disease had never changed it."

Respecting points so interesting and so mysterious, it is scarcely possible to refrain from speculation altogether. I have laid before you some attempts of able and thoughtful men to explain the main facts of the case: namely, the production of the disease by an animal poison; the prodigious increase in quantity of the specific virus within the body during the progress of the malady; and the extinguishment of the susceptibility of its influence in that individual thereafter. Without adopting either theory with implicit credence in its truth, I hold my judgment in suspense, until evidence more convincing shall appear, or until some better theory than either shall be propounded.

It is very certain, and it is not inconsistent with these theories, that the diseases of this group, which are all of them blood-diseases, do often leave permanent traces of their agency upon the general health, even when no local damage is apparent. We hear men say, "I have never been so well since I had the measles, or the typhus fever, in such a year:" and we hear this without much wonder, knowing that local mischief may lurk within, unrevealed by any legible outward signs. It is more surprising, but it is equally true, that the influence is sometimes for good. The system is disencumbered of some previous impediment to its perfect welfare. Of this mysterious ameliorating influence, which is the rarer of the two, I may give you one example.

A servant of a gentleman living in Belgrave Square was constantly ailing and weakly. His master procured for him, without avail, the best medical advice that London could furnish; and at one time put him into St. George's Hospital, with very small benefit or change in his condition. At length the man caught small-pox, and had it most severely and dangerously under the care, in his master's house, of the late Drs. Nevinson and Chambers. His life was despaired of. By and by a large mask of scab fell entire from his face, and he recovered, though frightfully seamed by the disorder. From that time for many years he lived in the enjoyment of thorough health and strength, such as he had not known before the attack of small-pox.

The subtle contaminating effluvia which proceed from the bodies of the sick enter the blood of those who catch the disorder, chiefly, I imagine, by being inhaled into the lungs in breathing. The poison may, perhaps, be capable of being spontaneously absorbed through the skin: and upon this supposition oil has been smeared over the surface with the view of shutting out the contagion of the plague. The virus may gain direct entrance into the blood; we know that it sometimes does so, for we ourselves insert it, in inoculation of the small-pox. Dr. Francis Home imparted measles by engrafting some of the blood of a person ill of that complaint; and subsequent attempts to excite the disease in that way have been equally successful. Some rash and unfortunate trials have proved that the plague is communicable by inoculation with matter from the buboes.

Endeavours have been made to estimate the distance to which the influence of different contagious emanations extends. The effluvia in small-pox, measles, and scarlet fever, are the most active; operate, I mean, at the greatest distance. In continued fevers they have a less range; and in the plague the diameter of the infectious circle is probably very small. Some have even supposed that the plague is communicable only by actual contact; but the opposite opinion seems the more likely, namely, that you may *touch* plague patients with impunity (as Bonaparte is known to have done

on a memorable occasion) if you avoid inhaling their breath, or the effluvia proceeding from their bodies.

The most important practical result of the experiments made by Dr. Haygarth and others, for determining the absolute distances to which the power of the contagion extends in different disorders was, that *where ventilation is complete*, in other words, where the gaseous poison is freely diluted with atmospheric air, the sphere of its operation is very limited.

It is an interesting subject of inquiry, worth glancing at for a moment, how far the power of different contagions is modified by differences of temperature. Small-pox is readily propagated either in hot or in cold regions; in Mexico near the Equator, in Greenland towards the Pole. The plague does not spread when the temperature is below 60° or above 90° Fahrenheit. The vaccine matter loses its property of producing the cow-pox if it be exposed for a certain time to extreme cold, or to a heat of 95°. Typhus fever, measles, and scarlet fever, are said to be of rare occurrence in the intertropical regions. Dr. Henry has turned these facts to useful account by proposing to decompose and destroy certain contagions lurking in fomites, by the operation of artificial heat.

Having thus pointed out many circumstances of interest, which are common to all, or nearly all, the diseases grouped together under the title of exanthemata, I may now proceed to a more particular account of those diseases in succession. And I shall begin with *continued fevers*; because, although they do not afford the best-marked examples of the collection of symptoms that compose Cullen's definition of the order, yet a right understanding of the practical points concerned in the management of these febrile diseases, will assist us materially towards a just conception of the modifications of treatment that may be required by the rest.

We hear continually, both in and out of the profession, many different species of fever spoken of. By the public, typhus fever, brain fever, bilious, putrid, low, nervous. And systematic writers are to the full as particular; mucous fever, ataxic, adynamic, gastro-enteric, typhoid, and so forth. Now this complexity of nomenclature is puzzling to the student, and misleads the public mind. Friends and parents ask anxiously what sort of fever the patient has: and medical men themselves often find it difficult to answer them. The subject is really more simple than at first it may seem to be; yet it is not quite so simple as I formerly supposed. For a long time I held, in common I believe with most English physicians, that no definite line of genuine distinction could be drawn between the various forms of continued fever met with in this country. I was indeed aware—it was impossible to be long engaged in hospital practice without becoming aware—that different epidemics presented very striking features of diversity and even of contrast—so as to suggest the frequent suspicion that the maladies composing them might be specifically distinct. Still, taking into account their strong general resemblance—finding that these like, yet varying forms were often more or less intermixed—noticing also that other distempers fluctuated in type, that within the last twenty years all acute disorders had assumed, in this town at least, an altered and a more asthenic character—I conceived, and I taught, that the differences to which I have adverted in the aspect and phenomena of continued fever, depended more upon what is called the epidemic constitution,—that is to say, more upon an acquired disposition of the human body produced by some obscure general influence, and therefore affecting the entire London community,—than upon any essential difference in the nature of the disease itself, or in the virus from which (as I believed) it sprang.

But I think so no longer. The Dr. Jenner of our time, with patience and sagacity worthy of the great name he bears, has traced out plain lines of division between two or three forms of continued fever, and especially between two forms which had been chiefly confounded together, and which we now call respectively *typhus* and *typhoid* fever. In the affinity of these names is still implied the similarity of the two disorders; but Dr. Jenner has shown, by evidence which quite satisfies my mind, that they differ notably and constantly in their symptoms and course, in their duration, in their comparative fatality, in the superficial markings which respectively belong to them and which warrant our classing them among the exanthemata, in the internal organic changes with which they are severally attended, and (what is the most im-

portant, the most conclusive, and the most difficult point to determine of all) in their exciting causes. For some reasons it may be regretted that names so much alike should have been given to diseases which are really distinct; yet even this may be not without its advantage, if it keep the attention of the observer on the alert to discriminate between the two kindred disorders. For my own part, I could have wished that typhoid fever had been named, as Dr. William Budd names it, *intestinal fever*.¹

A third form of continued fever, called the *relapsing* fever, is readily distinguishable by well-marked features of its own, when once its separate existence has been realized.

In sketching the main phenomena of continued fever I shall keep in view *typhus* as its typical form—and afterwards point out the characters which chiefly distinguish this from the *typhoid* disorder. In this way I hope to spare you the tiresomeness of listening to a detailed description of each of two diseases, which, after all, have very much in common.

Typhus fever does not not always commence in the same way. It may happen that for several days before the disease assumes its distinct and proper aspect, and before the patient is rendered unable to pursue his usual occupations, he is affected with certain morbid symptoms which may be considered premonitory of the fever; so that it is sometimes difficult to mark the precise beginning of the disease. These preliminary symptoms result apparently from an altered condition of the *nervous system*. The poison in the blood disturbs the functions of animal life before it causes any palpable derangement in the mechanism of the circulation. The expression of the patient's countenance alters; he becomes pale, languid, and abstracted. Those about him observe that he is looking very ill. He is feeble, and easily tired; reluctant to make any exertion of mind or body; listless, and apprehensive often of some impending evil. He loses his appetite; his tongue becomes white and inclined to tremble; his bowels are irregular, often confined, rarely affected with diarrhoea; his senses lose their natural delicacy. He has uneasiness or wandering pains in various parts of the body; and occasionally there is some giddiness: drowsiness perhaps during the day, and unsound and unrefreshing sleep at night. To collect all this into one expressive word, the patient evidently *droops*.

Much more commonly, however, these preliminary movements are altogether wanting: the disease sets in suddenly. Its regular onset is marked, very frequently indeed, by a *shivering fit*. Another common phenomenon at the period of the invasion is severe *headache*; pain or aching across the forehead, rarely in the temples, never at the back of the head. It is apt to begin during the night, or in the early morning. But this is not constantly the case. Sometimes there is a sense of heaviness and vertigo rather than headache. You will perceive also, even when there have been no premonitory circumstances, that symptoms arise, even thus early, which belong to the nervous system, and which denote some disturbance and alteration in the functions of sensation, thought, and voluntary motion. They are comprised under the general phrase "*febrile oppression*," and they are different from what we notice when pyrexia supervenes upon inflammation. You will obtain a clearer notion of what this term, *febrile oppression*, means, by watching at the bed-side of *one* patient in this disease, than by any description that I can give you. There is great inaptitude for the exertion of the power of thought, or of motion. The expression of the face is dull and heavy, absent, puzzled; its hue thick, and dusky. The patient presents very much the appearance of a person made stupid by drink; and he staggers a little when he attempts to walk. The muscular power is sensibly enfeebled: sometimes the patient will struggle against this; but in a few hours, or in a day or two at furthest, he takes to his bed.

These are the symptoms which mark the outset of the disease we are about to consider. They occur also, more or less distinctly, in the other disorders of the class in which I have placed continued fevers. In the plague, for example. The patients appear like people who are drunk. Now these symptoms result, no doubt, from

¹ It is a bare act of justice to record that so early as the spring of 1840, a paper was read before the Parisian Medical Society, by Dr. Alexander P. Stewart, in which the main distinctions between typhus and typhoid fever were clearly set forth. And in 1842 Dr. Bartlett's excellent book on Fever testifies to the same distinctions, as he had noticed them in the United States.

changes which are going on in the blood, and which make an early and a strong impression upon the nervous system. And there is another circumstance which, when it is observable, denotes a depressed state of the nervous power. Practitioners, sometimes, are in doubt whether the case may not be one of some visceral inflammation: or, perhaps, knowing it to be continued fever, they still think it expedient to *bleed* the patient. Now faintness or actual syncope is much more easily produced by the abstraction of blood, in *continued fevers*, that it is in *inflammations*: and this fact may occasionally be the means of distinguishing between incipient continued fever, attended, for instance, with catarrhal symptoms, and pure incipient pneumonia.

In order the more clearly to portray the course of continued fever, I shall divide it, as others have done, into periods: weekly periods. Not that there is any such period of seven days allotted to particular symptoms: but that in the simplest forms of the disease, when it runs its course most evenly and favourably, and therefore, we may suppose, the most *regularly* also, there is a succession of different *sets* of symptoms, which occupy each *about* that space of time: nearly enough to allow of my taking it as a help to the better *describing* the disease.

Many of the symptoms which occur during the first stage of the disorder—during the first week, we will say—are such as belong to the sanguiferous system. The pulse becomes more frequent than in health, there is increased heat of skin, and thirst; headache, and throbbing of the temples. The pulse varies considerably in different cases. Generally, I say, its frequency augments; but sometimes it is even slower than natural. The acceleration of the pulse is greatest (*cæteris paribus*) in those constitutions which are the most irritable. In young persons, in females, and in weak and delicate males, it will often rise, soon, to 120: while in stronger adults, it does not so early attain its maximum of frequency, and perhaps does not exceed 100 throughout the whole course of the disease. Should the pulse in any instance reach 130 or 140, the disease is severe: and the majority of such patients die. The absolute frequency of the pulse is not, however, of so much importance in typhus fever, as its steadiness. If it shift from one number to another, *that* affords a worse prognostic even than its being very frequent, provided it keeps at the same standard. It is almost always soft, soon becomes weak, and gradually gets weaker. Dr. Jenner affirms that in *typhus* fever, running an uncomplicated course, the pulse rises slowly in frequency to a certain point, preserves that rate of frequency for a variable period, and then as slowly falls: while in *typhoid* fever it rises and falls in a most irregular manner, to-day 120, to-morrow 90, the next day 120—without appreciable cause or consequence. The skin, during this period, is generally hot and dry, and it *feels* to a bystander very hot and *pungent*. The actual heat, however, is not so great as the sensation given to our hand might persuade us it was. Dr. Bateman found that, in a majority of the cases treated by him, the heat, as ascertained by the thermometer, was about 100°; and he never observed it higher than 104°. The thirst is usually troublesome for the first few days. The tongue becomes clammy or dry; sometimes it is clean and smooth; more often furred: its edges and tip will, perhaps, be red, then a white fur will begin, which either covers the central part of the tongue, or is divided by a straight brown streak which occupies its middle portion. This brown streak is often the first step to dryness and blackness of the tongue.

Slight and transient tenderness of the abdomen is not uncommon during the same period. Sometimes the belly is full and resonant, without being sensibly distended; sometimes it is even concave; most frequently of all it retains the natural qualities of health.

There is evidence, frequently, of a slight affection of the membrane lining the air-passages, from nearly the first: some notable quickness of respiration, and some diffused rhonchus and sibilus, audible through the stethoscope.

And among all the indications of increased action in the circulating system, the symptoms that relate to the nervous centres remain perceptible. The aspect of the patient is peculiar: the features are fixed and inexpressive; or expressive merely of apathy and indifference. If spoken to briskly, he responds; and although his sensibility seems blunted, his answers are, as yet, rational, and to the purpose. Delirium does not come on, in general, till towards the end of the first week. The muscular power is greatly depressed. The patient lies on his back, motionless; he sleeps but little, waking often; and the short snatches of repose which he seems to get, are

disturbed, apparently, by uneasy dreams; and he *fancies*, and says perhaps, that he does not sleep at all: or he lies with his eyes open, evidently awake, but insensible to all that is going on around him. To this condition Dr. Jenner applies the term *coma vigil*. It is much more common in typhus than in typhoid fever, if it be not peculiar to the former. Sometimes, even during the first stage of the disorder, the prostration of strength is so great, or the tendency to stupor and indifference is so marked, that the stools are passed under him as he lies in bed, without any apparent endeavour on the part of the patient to prevent it; and without any notice of his wants being made to his nurse. The urine, during the same stage, is scanty, and high-coloured, and ill-smelling often. Towards the very end of the first weekly period, the eruption which is peculiar to typhus fever commonly begins to show itself: but this is sometimes postponed to the next stage; and I shall describe it in connexion with the other symptoms that are apt to occur in the second week of the disorder.

It is seldom, except in very malignant forms of typhus fever, that death takes place during its primary stage.

LECTURE LXXXIV.

Typhus Fever, continued. Phenomena of the second week; Delirium, Mulberry Rash: of the third week; Recovery, or death in the way of Coma, of Apnœa, of Asthenia. Symptoms that precede and usher in those modes of dying. Typhoid Fever; points of distinction between it and Typhus in respect of symptoms, of modes of attack. Rose-coloured spots. Ulcerations of the Intestine.

IN the last lecture I commenced the consideration of that important disease, which has been best known, in this country, under the name of continued fever. I told you that I had been converted from my former belief in the unity of species of continued fever, by the researches of Dr. William Jenner, who has demonstrated the separate identity of at least three species, namely, typhus fever, typhoid fever, and relapsing fever. And I began to draw an outline of the general disease, keeping *typhus* fever before my mind, as its most formidable species. Sometimes this disorder is preceded by symptoms of a slighter disturbance of the system; more frequently it sets in suddenly, in the midst of apparent health. Whatever premonitory symptoms may take place, they indicate some alteration in the functions of the *nervous system*; upon which many pathologists have supposed that the first and most direct impression is made, by the exciting cause of the fever. But the exciting cause, in many cases, probably in all, is a specific poison received into the blood; and all analogy is in favour of the belief that the primary change is wrought upon the *blood* itself. The whole mass of the blood is gradually vitiated; and the first evidence of the circulation of this altered fluid, is depression of the powers and functions of animal life. Among the earlier symptoms of the declared disease, shivering, headache, and febrile oppression, take the lead.

For the convenience of description I divided the course of the disorder into three weekly stages: not that it necessarily *runs* its course in three weeks, but because the sets of symptoms which succeed each other while the disease is in progress, occupy, in the cases which seem to proceed the most regularly, *about* the space of seven days each.

Now the symptoms present during the first week are expressive of disorder both of the sanguiferous and of the nervous system. The patient is hot, flushed perhaps, and thirsty, and he has a frequent and hard pulse. Besides this he manifests indifference, and stupor; his senses are blunted, his intelligence is diminished. His muscular strength is reduced in a remarkable manner; so that he cannot sit up; in many cases he cannot even lie on his side, or turn himself about well in bed, but remains in the supine position; and if he be purged by medicine, or spontaneously, the stools are apt

to pass from him into the bed, without his knowing it, or without his taking any care to prevent it. This, however, is more common, and more marked, in the second period or week; the phenomena of which I next go on to sketch.

The changes that occur are usually the following:—The pulse becomes more frequent, weaker, and more compressible. The tongue grows drier and browner. More sordes, and of a darker colour, accumulate on the teeth and lips: and it is in this period that delirium is most apt to ensue; and that certain *eruptions* are most often observed. But the symptoms that relate to the nervous system are often still the most prominent. The patient generally loses his *headache*. His voluntary movements, however, become very much weakened, and are sometimes exercised irregularly. The posture which the patient in this stage almost always assumes is, I say, indicative of this weakness; he lies on his back, and he *sinks down in the bed*, slips towards the foot of the bed. He is unable to make or bear that degree of voluntary exertion which would be necessary to place him upon his side. Hence we hail it as a good omen—because it is an indication that the patient still retains some strength—if we find him on his side, or even on his back with his knees drawn up. Other proofs of muscular debility, approaching to palsy, are apt to present themselves. The voice becomes feeble; the patient can scarcely utter an audible sound. Perhaps he is unable to swallow. This is a very bad symptom, though it is one that has been recovered from. Sometimes it seems that the power of deglutition is not lost, but the sick man is too listless to try to swallow: or the dry and parched state of his tongue and throat render it difficult and painful for him to attempt to do so. The patient is apt to lie with his mouth open: and breathing thus through the mouth tends to dry the tongue. Hence it is well to desire him to swallow a mouthful or two of water, and so to moisten his tongue, before you decide upon the state of that organ, or upon his facility of deglutition. Often, in bad cases especially, there are little convulsive startings of the tendons, (*subsultus tendinum* is the technical name of the symptom,) and other irregular and involuntary actions of the muscles: tremulous movements, especially of the tongue and of the hands; and sometimes the sick person is unable to put out his tongue at all. There are two symptoms which, in the majority of instances, present themselves most obviously in the second week of the fever, and which deserve your particular attention: I mean delirium, and the eruption which belongs to the disease.

The delirium is peculiar. The patient wanders, at first, in the night only; and the delirium commonly appears on his awaking from disturbed sleep. Sometimes he is desirous of getting up, and talks incessantly and earnestly in a loud voice, and can only be kept in bed by the imposition of some restraint. Usually, however, his rambling is of a tranquil kind, and without agitation. His mind seems elsewhere: he is inattentive to all that passes around him; but he lies still, muttering disjointed words or sentences, like a man talking in his dreams. From this state of *typhomania* the patient may sometimes be roused by loud speaking addressed to him, or by the sight of a strange face; so that though incoherent and delirious just before, he may become collected when his medical attendant enters the room. But he presently relapses. During the delirious state there is a great deficiency of sensation, and insensibility to impressions. The patient is deaf. This deafness you may hear spoken of as being a good omen, or favourable sign; but it is only so by comparison: it indicates a condition of brain less perilous than its opposite, in which the sense of hearing is morbidly acute. Imperfection or loss of vision is much rarer, and much more alarming, than deafness; yet the eye is generally dull—unlike the brilliant eye of acute phrenitis; it corresponds with the expression of the countenance, which is perplexed rather than wild. Sometimes, however, as the disease advances, black spots, like flies on the wing, *muscæ volitantes*, appear before the patient's eyes: in consequence, it is presumed, of partial insensibility of the retina. The patient attempts to grasp or catch these in the air, or to pick them from the bed clothes. This is called *flocitatio*. After these symptoms recovery is not common. The mouth and tongue are dry: yet the patient no longer complains of thirst. The taste, the smell, the sense of touch, are all impaired. One trivial yet expressive mark of this dulness of the senses, mentioned by a recent author, is that the flies crawl, unnoticed, over the patient's face. Even external ulceration may occur, especially about the hips and sacrum, and go on to gangrene, without any complaint of pain from him. He seems

altogether careless about the issue of his disorder. If, at this period of the fever, you ask him how he does, he will probably declare that he is quite well. I have already alluded to the involuntary passage of the *fæces*: this may depend, in part, especially in the advanced stages of the disorder, upon debility or paralysis of the sphincter muscles. The urine also dribbles away frequently; and these are points which must always be looked after; first, for the sake of keeping the patient as clean and dry as possible, the irritation of the urine and *fæcal* matters tending to produce sloughing ulceration; and, secondly, with the view of preventing the bladder from becoming unduly distended. Retention of urine, and all its bad consequences, may otherwise occur. It is a good general rule, therefore, to examine the hypogastric region every day with the hand: and also to ask to *see* the urine, not for any purpose of prognosis, but to ascertain that it is regularly discharged.

The eruption which is peculiar to and distinctive of typhus fever, is called by Dr. Jenner the *mulberry rash*. I follow his account of it with perfect confidence in his fidelity as a describer. It commences usually from the fifth to the eighth day of the disease; sometimes later. After the third day of the eruption no fresh spots appear. In this particular it resembles, as we shall see hereafter, the eruption of small-pox. It disappears in the course of the third week of the disorder.

The characters of the rash vary with its age. It is never papular, but consists, at first, of very slightly elevated spots of a dusky pink colour. Each spot is flattened on its surface, irregular in outline, fades insensibly into the hue of the surrounding skin, and disappears completely under the pressure of one's finger. The larger spots, more irregular than the smaller, appear to be formed by the coalescence of two or more of them.

In two or three days these spots undergo a marked change. They are no longer elevated, become darker, dingier, and rather more defined; and now they fade only, without disappearing, under pressure. From this condition the spots, in most instances, grow paler, pass into faintly marked reddish brown stains, and finally disappear. In some others a third stage is reached. The centres of the spots take a dark purple colour, and remain unaltered by pressure, although their circumferences fade; or the entire spots change into true petechiæ — *i. e.*, into spots of a dusky crimson or purple colour, quite flat, with a well defined margin, and unaffected by pressure. These petechial spots result from a minute extravasation of blood beneath the cuticle. They occur most frequently on the back, at the bend of the elbow, and in the groin.

The spots composing this mulberry rash are generally very numerous, set closely together, and sometimes they almost cover the skin. They are usually situated on the trunk and extremities, occasionally on the trunk only, now and then they are seen on the face. Each spot remains visible till the whole rash vanishes. To this rule there is one exception. The eruption sometimes shows itself first on the backs of the hands, and disappears from those parts within twenty-four hours. When numerous, the spots have not all the same depth of colour; some being paler than others, and appearing as if seen beneath the cuticle. Hence the surface has a mottled look. Our wards at the Middlesex Hospital in 1838 were full of this form of fever. Not a case, I believe, presented itself without these spots. We spoke of it familiarly as the *spotted fever*; or (from the resemblance the rash bore to that of measles, hereafter to be described) as the *rubeoloid fever*.

The spots which I have been describing, those at least which had reached their second stage, have been found to remain visible upon the surface of the dead body, when death has ensued before their natural time of disappearance. The petechial spots also are persistent. And after death, as well as during life, the spots on the undermost parts of the body are the darkest in colour. This difference seems to be owing to their depending position.

Finally, with respect to this mulberry rash. Dr. Jenner states that in patients less than 15 years old it is mostly either absent, or pale in hue, and scanty in quantity. And the mortality from typhus at this early age is proportionally trifling, not more than 2 or 3 per cent.: while in persons more than 50 years of age it is about 56 per cent., and in them the rash is always present, and ordinarily dark and abundant.

There is another eruption described by the French as *occurring* in this disease without being *peculiar* to it. In this country it is now rare; but it used, when the hot plan of treatment was in vogue, to be very common indeed here, in various febrile

complaints: and it was, and is, apparently connected with copious sweating. *Sudamina*, the vesicles composing the eruption are called. They are small, hemispherical, transparent elevations of the cuticle, containing a clear watery fluid. The vesicles are from a quarter of a line to half a line in diameter; they have no red bases; and they are so perfectly pellucid, that when you look upon them in a direction perpendicular to the skin on which they stand, they may readily elude observation. Viewed sideways, they present bright surfaces, and look like so many drops of water, and you may feel with your hand that they *roughen* the part affected with them. These sudamina are mostly met with on the thorax, along the sides of the neck, and about the axillæ. By degrees, the limpid fluid disappears, and they shrivel up; the cuticle becomes wrinkled, and dries into a whitish powder.

Occasionally these miliary vesicles are so common as to give a character to an epidemic. Dr. Ormerod has described, in his *Clinical Observations on Continued Fever*, an epidemic of this kind which was prevalent here in the spring of 1847, chiefly among the Irish newly arrived in London. He states that the sudamina presented themselves "irrespective of any tendency to profuse perspiration."

Dr. Jenner is of opinion that age has something to do with the occurrence of these miliary vesicles; and that they are rarely seen on persons who are more than 40 years old. They remain after life has departed.

It is in the course of this second week of the disease that, in typhus fever, death is most apt to take place. Among 25 fatal cases noted by Dr. Jenner, 9 deaths only occurred after the 15th day; not one after the 20th.

As the disorder approaches its fatal termination, symptoms which are not unfitly called *putrid* very often show themselves: a peculiar fætor is exhaled by the patient's body; his tongue becomes dry, black, and fissured; and he is perhaps unable to protrude it when asked to do so; his teeth are covered with dark sordes; sloughs form from the mere pressure of the bed on which he lies; in extreme cases the toes have mortified; and Dr. Roupell relates one terrible instance in which both legs rotted away to the bones, which it became necessary to saw through: yet this patient recovered.

During the third week of typhus fever, the patient's chance of recovery improves; unless indeed some local mischief which pre-existed, or which has sprung up during the course of the fever, shuts out or obscures this more favourable view.

When the disorder is about to end favourably, the more formidable of the symptoms diminish and abate. The patient begins again to attend to questions that are put to him; the air of stupor which had hung over his countenance clears away; he once more shows an interest in what is going on around him; the temperature of his skin becomes more natural; the tongue moist and cleaner at its edges; and the frequency of the pulse is less. The evacuations from the bowels gradually regain their natural qualities; and the patient is aware when the necessity for passing them, or for emptying his bladder, arrives, and he gives notice, or asks for assistance. Generally, at the same time with these tokens of improvement, the emaciation which has taken place becomes remarkably conspicuous; perhaps it is the more observable, on account of the patient's resuming a more natural expression of countenance.

In many instances, the amendment is so gradual that we can scarcely say when it begins. In other cases the favourable crisis is preceded by an aggravation of most of the former symptoms, and a marked increase of the general distress. This is a very curious circumstance: and it did not escape the notice of our great dramatist.

Before the curing of a strong disease,
Even in the instant of repair and health,
The fit is strongest. Evils that take leave,
In their departure most of all show evil.

Certain evacuations are also sometimes observed to accompany or to be connected with the favourable change; and the most common of these is the evacuation of sweating.

On the other hand, when the disease is about to terminate in death, that event may take place in different ways; in either of those modes, in short, which I took some pains to distinguish in the earlier part of this course of lectures. I told you then that I had been taught the importance of studying the tendency to this or that

mode of dying, in reference especially to fever by Dr. Alison. My own experience has since sufficiently approved to me the wisdom of his teaching. Cullen inculcates the necessity of "obviating the tendency to death." To do so, we must ascertain the direction of that tendency. We do not so much *cure* these exanthematous maladies, as keep our patients alive while they are recovering. If we would prevent their dying, we must know in what manner they are in danger of dying.

The most common mode of death in typhus fever is certainly that of *coma*. The organic life survives the animal life. The muttering, half-conscious, dream-like stupor, from which the patient may be roused for a while, becomes, by degrees, more profound, and death begins at the head. This mode of death, occurring in the second or third week of the fever, is associated frequently, with the symptoms of putrescency already described. But as the stupor deepens, the pulse generally grows weak, and the extremities become cold. So that death does not come purely in the way of *coma*; but we have a compound of *coma* and *asthenia*, in which the *coma* takes the lead.

Now *coma* may result from at least two different kinds of cause. One cause is pressure, which is mechanical. Another, which is probably chemical, is the circulation of some noxious or narcotic substance (such as opium) in the blood. And there are, doubtless, many physical conditions of the nervous mass itself which are capable of arresting the cerebral functions, and producing *coma*. To which kind of cause are we to ascribe the stupor that supervenes during the progress of fever? That is an interesting, and in reference to practice, an important, question.

Physicians have diligently attempted its solution, by examining the dead brain. I cannot tell you how often I have looked, and looked in vain, for some palpable disorganization, or some effusion implying pressure. All who are familiar with the dead-house of a hospital are aware that this fruitless search for some physical explanation of the comatose state, after death by fever, is of very common occurrence.

The unnatural conditions that have been sometimes noted are—slightly diminished consistence of the substance of the brain; congestion of its blood-vessels, marked by red points on its cut surface; undue fulness of the vessels of the *dura* and *pia mater*, with, occasionally, thin coagula or films of blood in the cavity of the arachnoid; scanty effusions of thin watery liquid in the lateral ventricles, or in the meshes of the *pia mater*; and diminished cohesion between the membranes and the surface of the convolutions, so as to admit of their separation with unusual facility. Now to what conclusion do these facts lead us? Why, in the first place, to the conclusion that those pathologists are in error who maintain (as Dr. Clutterbuck did, for whose experience and talents I always entertained a sincere respect), that the essence of continued fever is *inflammation of the brain*. Not only do we fail to discover, in many instances, any traces of inflammation, upon inspecting the dead brain, but we find that, during the life of the patient, measures which would be likely to aggravate any inflammatory mischief—strong stimulants, for example, wine or brandy,—do actually and obviously, in cases innumerable, relieve the comatose symptoms, and benefit the patient. The inference seems unavoidable, that the *coma*, in such cases, has some other cause than that mechanical pressure which arises sometimes from the effusion of fluid upon the surface of the brain, or within its ventricles; and that other cause is supplied by the poisoned blood. Here again we may adopt the pathology of Shakspeare:

The life of all his blood
Is touched corruptibly: and his pure brain
(Which some suppose the soul's frail dwelling-house)
Doth by the idle comments that it makes
Foretell the ending of mortality.

In some malign epidemics the nervous system is overwhelmed at once, in the very outset, by the force of the poison. The patient becomes stupid or bewildered; his surface is cold, clammy, purplish, and his pulse feeble: the *coma* rapidly augments, and death may ensue within twenty-four hours. We sometimes see this fearful train of symptoms in small-pox; and still more often and more strikingly in the worst forms of scarlet fever. I believe that in these cases there is no deviation, cognisable by our senses, from the healthy texture and appearance of the parts within the skull.

Nevertheless, there may be, and there not seldom is, in these fevers, actual inflam-

mation of the brain or of its membranes : but this is an incidental complication. We conjecture that, in addition to the influence of the poison upon the nervous system, there may be a low degree of inflammation going on within the head, when we find it externally hot, when the patient has flushed cheeks, and a vascular eye, and complains of dull headache. And there are some instances in which we recognise more distinctly the outward signs of encephalitis—severe pain in the head, high and fierce delirium, intolerance of light and of sound, with much heat of skin, and a hard pulse. When coma succeeds such symptoms as these, we naturally ascribe it, in part at least, to the effects of the inflammation : and rightly, for we find traces of inflammation after death ; considerable serous effusion into the cerebral ventricles ; shreds of coagulable lymph upon the membranes ; and more rarely suppuration. I suspect that genuine encephalitis, which is of course attended with pyrexia, is sometimes mistaken for continued fever with intercurrent inflammation of the brain. Great attention, and some skill and judgment, are required for discriminating those cases of fever in which such inflammation occurs, and for directing the appropriate treatment.

The death in fever by *apnoea* is certainly much rarer than that by coma, yet it is not very unfrequent. It often mingles itself with the death by coma. From the earliest period of the fever we may, in most cases, notice some increased quickness of respiration, which is not entirely owing to the mere fever, or to acceleration of the circulation ; for the ear, when applied to the parietes of the chest, discovers rhonchus, and sibilus, at least. Frequently there is considerable dyspnoea for some hours, or for a day or two, before death : and this may be apparent only, in consequence of the stupor ; or it may be real, and proceeding either from more or less of pulmonary collapse, or from a low form of pneumonia, which, by interfering with the due arterialization of the blood, may aggravate, or even give rise to the coma : and such pneumonia is apt to be masked by the fever ; declaring itself by none of the ordinary symptoms of cough, rust-coloured sputa, or pain in the thorax. The inflammation, thus latent, is discoverable, however, by the sense of hearing.

What account does dissection give us of the condition of the lungs after death from continued fever ? Why, the most notable, and probably the commonest morbid state is that kind of condensation which indicates collapse of the lungs ; and it is met with chiefly at their posterior part and in its diffused form — sometimes however dispersed through them, and in its lobular form. M. Louis found this change, which he calls *carnification*, in 19 out of 45 instances of death from typhoid fever. It was observed by Dr. Wm. Gairdner in the lungs of many of those who fell victims to the Edinburgh epidemic of 1847. It occurred in each of the three species, but more rarely in the relapsing than in the typhoid and typhus fevers.

As the bronchial tubes are very apt to be clogged with viscid mucus, while the muscular power of the patient is so much reduced by the disease as greatly to impair the force and effectiveness of the acts of inspiration, you will not be surprised that pulmonary collapse should often accompany the course, and aggravate the danger of continued fever. Another unnatural appearance met with in the pulmonary substance is engorgement : a state similar to that which occurs in the first stage of pneumonia. But here the engorgement is probably in a great measure mechanical, and takes place during the last few days of the patient's life. As the vital powers diminish, the laws which govern the physical world resume their empire. The fluids, and the blood especially, accumulate in the most depending parts of the viscera ; and the lower and hindmost portions of the lungs in particular become loaded. But besides this, it is not unusual to find large portions of the lungs in a state of hepatization, and even infiltrated with pus. Less frequently, and in those cases principally in which the putrid symptoms have been most marked, the lung passes into a gangrenous state.

The mode of death by *asthenia* or syncope in typhus fever is not very common *as existing by itself* ; but it is often combined with one or both of the other two modes. Death beginning at the heart is more frequently seen in the *typhoid* disease ; to which I may now turn.

The main features, as I have endeavoured to paint them, are the same, or very similar, in both of these two allied diseases. It remains for me therefore to dwell on those only which chiefly serve to discriminate them.

In the first place, then, typhoid fever commences more often insidiously, and with

premonitory symptoms — more gradually — than typhus. Chomel gives the following comparative account, deduced from the exact observation of 112 patients in this particular. In 73 of these cases the invasion of the disease was sudden, without any warning, in the midst of apparent good health. In 39 there were prelusive circumstances.

The aspect of the patient in typhoid fever, though heavy and oppressed, differs remarkably from that of the sufferer under typhus: its hue is less dusky or muddy-looking, its expression less dull and stupid, more anxious, less apathetic; and sometimes, on the occurrence of delirium, it is even vivacious. The delirium is decidedly more active; and the patients are more disposed to try to get out of bed.

A striking characteristic of typhoid fever, and very important in relation to its treatment, and to an ulcerated condition of the intestines which I shall presently describe, is the prevalence of diarrhœa. Often this is an early symptom; sometimes it is postponed to the latter part of the first or the beginning of the second week. It is either spontaneous, or it continues after the operation of a dose of purgative medicine. Pain in the abdomen frequently precedes and accompanies it. Whenever it occurs, the stools are for the most part, loose and frequent: and either of a dark colour, and fetid, or of a yellow-ochre appearance, like pea-soup somewhat. If you make pressure upon the abdomen, you will find it unnaturally hard and resisting, as though its walls were made of pasteboard, tympanitic, sometimes very much distended, but, whether large or not, Dr. Jenner states that "its shape is invariably the same, and somewhat peculiar. Its convexity is from side to side, and not from above downward. The patient is never pot-bellied, but tub-shaped; the cause probably being that the flatus occupies the colon, ascending, descending, and transverse." Frequently, uneasiness is manifested when pressure is made on the belly, particularly over the cæcal region: and another symptom, not commonly met with in other diseases, is usually noticeable in the first stage of this, viz., a slight gurgling movement, evidently from the intermixture of liquid and gas within the bowel, which movement becomes audible, or palpable to the hand, upon pressing the same region. This symptom is still more common in the more advanced stages of the disorder. It is of rare occurrence in *typhus* fever.

As the disease proceeds, so does the diarrhœa; from three to six stools, or even more, occurring daily. When they take place involuntarily, when they are passed in the bed without notice on the part of the patient, they add materially to his danger by the irritation and the sores which are apt to result from their contact with the skin. There is seldom much pain of the abdomen now complained of by the patient; but if you make pressure, especially about the situation of the cæcum, you may often remark that he winces, or that a transient expression of suffering passes across his features. The character of the evacuations remains the same, and is almost distinctive of the disease; thin, yellowish, ochrey, like pea-soup. When, in fever, such stools persist day after day, and several of them every day, you may safely infer that there is ulceration of the bowels, although there should be no pain complained of even when the abdomen is pressed.

And the same conclusion will become still more certain when *hæmorrhage* from the bowels occurs, as it is apt to do, in this stage of the fever. It often takes place unexpectedly, sometimes in considerable quantity, and rapidly exhausts the patient; or it recurs at intervals to a smaller amount, wasting his strength as surely, though more slowly. The bleeding is probably owing, in general, to the division or opening of some of the mesenteric veins by the ulcerating process which I shall more fully describe by and by. This is not, however, a necessary consequence of the ulceration; for the vessels are usually obliterated previously to their erosion. Sometimes blood may be thus poured into the bowels without being voided. Andral relates a case in which a man died suddenly and unexpectedly at an advanced period of typhoid fever. Large clots of black blood filled the lower two-thirds of the small intestines, which were crowded with patches of ulceration. No part of the blood had passed the valve of the cæcum.

Hæmorrhage from the bowels may occur in continued fever in another way: in connexion with other putrid symptoms, petechiæ, purple spots, bruise-like blotches, and extreme depression of the vital power. In these cases the hæmorrhage is strictly of a passive kind, and it is a symptom of the worst omen. Like those effusions of

blood from the same parts that happen in scurvy and purpura, it depends upon a morbid condition of the blood. This is no matter of speculation, for by this time the sensible qualities of the blood are manifestly changed; its natural tendency to coagulate when withdrawn from the body is diminished, the crassamentum is large and loose, and fills the cup, and sometimes is rather an incoherent sediment than a clot. But hæmorrhage from this cause belongs rather to *typhus* fever, and in that species of fever it rarely happens from any other cause.

Another distinctive mark between typhoid and typhus fevers, is the character of their respective eruptions. That of the latter I have already described. It is strikingly in contrast with the eruption of the former.

The typhoid eruption is papular, or pimply. It consists of little circular spots of a bright rose colour, which fade insensibly into the hue of the neighbouring skin. They are slightly elevated, with round heads which never become vesicular, nor petechial. From first to last these spots disappear completely under pressure, and reappear when the pressure is taken away. Each papula lasts about three days. Others follow. Ordinarily the number present at one time is from six to twenty. Occasionally there is one only. Sometimes there are more than one hundred.

These spots begin to show themselves, generally, during the second week of the disease; and fresh spots come out every day or two till the third week, in the course of which they cease to appear, except in cases of relapse, when they also may recur with the other symptoms. Dr. Jenner holds that this species of fever is over by the thirtieth day, since, under ordinary circumstances, no fresh spots are seen after that day. Of course the *illness* may continue much longer — protracted by the effects of the fever, or by pre-existing local complications.

The spots peculiar to typhoid fever do not remain visible on the dead body.

It may not be superfluous to caution you against mistaking *flea-bites*, which are common to nearly all our hospital patients, for this specific eruption which is peculiar to fever patients. The round red stain, with a dark point for its centre, sufficiently distinguishes the mark of the insect from the rose-coloured spot of the disease.

There are certain differences to be sometimes noted in regard to the appearances of the tongue in the two diseases. It is oftener moist throughout the disease in typhoid than in typhus fever; and when dry, more frequently red, and as it were glazed. Generally, if brown at all, it is of a yellowish instead of a blackish brown. Dr. Jenner says, that “the small dry tongue, with red tip and edges, smooth, furred of a pale brownish yellow, and fissured, the surface seen between the fissures being of a deep red—may be considered differentially as a diagnostic sign of typhoid fever.”

With respect to the comparative *duration* of the two diseases, the same observer found that the average duration of the fatal cases of typhoid fever seen by him was twenty-two days, of typhus fever fourteen days. “Half the cases of typhoid fever survived the twentieth day of the disease. Not a single case of typhus fever survived the twentieth day.”

And it is in the more protracted cases of typhoid fever that death is chiefly apt to occur in the way of *asthenia*. In some instances it seems to take place from mere *debility of the heart*, there having been no pulmonary embarrassment, and the head having remained clear. Death, in such cases, is preceded by those symptoms of debility which have been already described. The pulse becomes small, and weak, and like a thread; the patient lies on his back, and sinks down in the bed; the features sharpen; the eyes are hollow, and dim, as though glazed; the sphincter muscles fail to contract; the extremities grow cold; cold sweats appear on different parts of the body; and at length the heart ceases to beat, and the patient to exist.

Death occurring in this manner does not, I say, occur *early*. It happens at an advanced period of the disease. It is noticed sometimes in persons who have been largely bled, or too actively depleted at the commencement of the fever; and in those who have suffered a good deal from *diarrhœa*. In short, as death in continued fever in the way of coma, and in the way of apnoea, is connected often with morbid conditions of the head and chest respectively, so death, in fever, occurring purely or *chiefly* by *asthenia*, connects itself with morbid conditions existing within the belly.

And in typhoid fevers we discover within the abdomen vestiges of mischief so constant and definite, and so different from what we meet with in typhus, as to have led first to suspicions, then to a closer scrutiny of facts, and finally to what I deem full

proof that these two disorders are as distinct the one from the other, as scarlet fever is distinct from small-pox. To these morbid conditions, then, so striking, and so constantly to be noticed within the abdomens of those who die of typhoid fever, I have now to invite your attention.

I need scarcely remind you that the intestinal canal is largely furnished, on its inner surface, with glands, or follicles, which consist of little more than crypts, and of which the precise office has not yet, I think, been accurately determined. Some of these glands are sprinkled (one may almost say at random) over the whole tract of mucous surface. These are accordingly called *solitary glands*. Till I was better instructed by Professor Todd, I used to speak of them as being the glands of *Brunner*; whereas the glands discovered and described by that anatomist are limited to the duodenum. Other glands or follicles are collected into groups, and are named *glandulæ agminatæ*, or often the glands of *Peyer*, who has given a capital description of them. Now the arrangement of these glands of Peyer is peculiar; and in reference to the morbid anatomy of typhoid fever, very necessary to be known. They are met with in the ileum alone: the groups are, mostly, oblong in form; and they occupy that part of the bowel which is opposite its mesenteric attachment. They are largest, and most numerous, and consequently most thickly set, in the lower end of the ileum, which, in some instances, is almost entirely covered with them: they are found also upon the ileo-cæcal valve; but beyond that they do not go in that direction. Ascending from the cæcum towards the jejunum, these groups or patches become smaller, shorter, more circular, and less numerous; they are separated by longer and longer intervals, till at last they cease to be visible at all. Where there are valvulæ conniventes, there the situation of these patches is very obvious; for the valvulæ conniventes are interrupted, and never run across them. This fact has sometimes led to curious mistakes. I have seen in the museum of the College of Surgeons a preparation put up by Mr. John Hunter (but not labelled I presume by him) professing to be an example of the destruction of portions of the valvulæ conniventes by ulceration. It is nothing more than one of those natural patches, rather more plainly developed than usual.

These glands, in their healthy state, are much more conspicuous in some bodies than in others. You may see, if you look at them attentively, that each patch is made up of a congeries of mucous follicles, of which the *orifices* are obscurely apparent. Now the main alterations met with in the abdomen after death, in typhoid fever, are alterations of these very glands: of the solitary glands, to wit; and still more constantly and remarkably of the agminate glands.

The changes which these glands undergo are of the following kind. In the first place they become enlarged, and more *perceptible* than they are in their natural state. They then present a greyish transparent surface, dotted over with black points; which black points mark, I conceive, the excretory mouths of the several follicles. This appearance, however, which has been likened to that of the recently shaven beard, is not necessarily associated, I believe, with disease. Then, as the inflammation, for such it is, advances, the patch becomes reddish, perhaps; and the follicles burst, or ulcerate, or slough away: not altogether, but partially and by piecemeal: so that an irregular ragged ulcer is generally left, having thickened edges. Sometimes, however, the follicles disappear without there being much redness or thickening: the

FIG. 183.

Solitary gland of small intestine. After Boehm.

FIG. 184.

Part of a patch of the so-called Peyer's glands, magnified, showing the various forms of the sacculi, with their zone of foramina. The rest of the membrane marked with Lieberkühn's follicles and sprinkled with villi. After Boehm.

mucous membrane immediately adjacent, and even the remaining part of the patch of follicles, being pale, and level. Sometimes the patch puffs up into a sort of fungous swelling, in which all trace of the follicular structure is lost. The colour of the ulcerated surface is various, as well as its form and appearance. Sometimes it is pale and grey; sometimes red; oftentimes yellow, as if the exposed cellular and other tissues were stained by the ochrey fluid which had been poured from the bowels during life. What I have hitherto stated relates to Peyer's glands; but the solitary glands participate, usually, in the change. They become, in the first place, large and hard, and present a whitish coloured projection from the surface, which, by a mistaken analogy, has been sometimes called a pustule. At length, a loss of substance takes place in these also; beginning at the summit of each, and producing a small, but sometimes a deep ulcer.

Fig. 185.

Ulceration of the glands of Peyer, with enlargement of the mesenteric ganglions. From a specimen in Dr. Gross' cabinet.

And of these changes it is further to be observed, that they are more common, more numerous, more extensive, more advanced, in proportion as we approach the cæcum. It is natural that we should meet with *more* ulcers near the cæcal valve, because there are more glands there; but undoubtedly the ulcers are (in general) *further advanced* there than higher up in the bowel.

Going along with this ulceration of the mucous glands of the intestines, and above all of the aggregate glands of the ileum, you will frequently find inflammation (*i. e.*, redness, hardness, and swelling) of the corresponding *mesenteric* glands. This would seem to be a consequence of the inflammation and ulceration of the mucous glands. The affection of the mesenteric glands is, I conceive, secondary; and bears the same relation to the ulcers seen in the bowel, as a bubo in the groin bears to a chancre on the glans penis.

These alterations are extremely interesting, because they afford a reasonable explanation of many of the symptoms of typhoid fever. They account for the diarrhœa. They account for the commonest form of hæmorrhage from the bowels: in one instance Dr. Jenner found that water, thrown into the superior mesenteric artery, welled forth freely from the edges of a ragged ulcer not far from the ileo-cæcal valve. They account also for the uneasiness or pain which is experienced when the abdomen is pressed, and teach us why that uneasiness is greatest in the situation of the cæcum. Nay, we can even understand why, although these ulcerations exist, there may be *no* pain occasioned by them. This may be partly owing to the general insensibility to impressions and sensations of all kinds produced by the stupor; but partly, also, it probably depends upon the depth to which the ulceration goes. The mucous tissues are possessed of but little sensibility even under inflammation; but if the muscular and peritoneal coats become involved in the inflammatory process, then pain begins to be felt. I remember, a few years ago, attending a young lady ill of fever, with a very well-informed practitioner, but one of the old school, for he had not turned his attention much to the state of the intestines in that disease. One day we learned that our patient had had hæmorrhage; from the uterus her friends supposed; but when I saw the discharge, I was made certain, by its appearance, and by its odour, though it was not mixed with any feces, that it had come from the bowels; and I stated my conviction that there was ulceration in the lower portion of the ileum. But she had no pain in the abdomen. You might press any part of it without exciting the smallest uneasiness. So, distrustful of my opinion, they called in an eminent accoucheur, who also pressed and examined the belly; but neither could he detect any tenderness or undue sensibility. He next examined the uterus *per vaginam*; but could discover nothing wrong there. Some few nights afterwards the general practitioner was called out of his bed to this patient. He was told that the hæmorrhage (or flooding as they called it, for they persisted in believing that it was uterine,) had returned; and before he arrived at the house the patient was dead.

We next day opened the body together. The uterus was perfectly natural; there was no vestige of discharge or bleeding in the vagina; but the ileum, for about a foot above its entrance into the cæcum, was in a state of superficial but ragged ulceration, and universally red and besmeared with blood. I mention this as a strong fact in illustration of the possibility of there being much disorganization of the inner surface of the intestines, without any pain to reveal it.

Now the alterations I have last been sketching—the thickening, redness, tumefaction, and ulceration or sloughing of the glands of Peyer, and also of the solitary glands, are met with, almost constantly, in some epidemics of continued fever, and are absent, almost constantly, in others. The kind of fever with which I was conversant in London for ten years before the first arrival of the cholera in this country, I now know to have been *typhoid* fever. The antiphlogistic regimen was indispensable at the outset of the disorder: in many instances blood-letting, either general or topical, seemed to be required, appeared to do good, and certainly was well borne: in well-ventilated wards the disease showed no strong tendency to spread: the mortality was very moderate. About the rose-coloured spots upon the skin I can say nothing, for I did not look for them; but the glands of Peyer, according to my own experience of the fatal cases, were almost invariably affected. Subsequent epidemics, I may specify particularly that of 1838, offered a marked contrast in all these points. A large per centage of those who contracted the fever died: the disorder was propagated from hospital patients to nurses and students: after death, we could not detect any disease of the agminate or other glands of the intestine: the peculiar mottled rash scarcely ever failed to show itself: we were taught by experience to refrain as much as possible from abstracting blood: and almost from the beginning, or quite, we found it necessary to sustain our patients by a liberal allowance of strong animal broths, and even of wine. An epidemic, of which I witnessed a portion in Edinburgh in 1820, was without intestinal ulcers. Chomel, during five years' investigation of this matter in the *Hôtel Dieu*, never met with an exception to the general rule of their occurrence, or of some degree or form of that sort of alteration of the mucous glands, of which the ulcer is the final stage: and the experience of Louis is to the same effect.

Dr. Carpenter has shown it to be probable that the natural office of the glandulæ agminatæ is to eliminate decomposing and noxious matters from the blood, and to discharge them into the intestinal canal: and Dr. C. B. Williams advances the reasonable suggestion, that the ulceration so constantly met with of those glands in typhoid fever may result from the continued operation of the poison of that disease, thus escaping.

When these internal ulcers do occur, is the disease, as is popularly supposed, always or necessarily fatal? By no means. It *may* be fatal, in more ways than one. It may lead to death, by exhausting diarrhœa, in the way of slow asthenia; it may kill by laying open a large mesenteric blood-vessel, and so producing copious hæmorrhage and mortal syncope; it may, and often does, destroy the patient, by *perforation* of the bowel: the ulcer penetrates the mucous and muscular coats, and reaches the peritoneum; and sometimes that membrane gives way, and sometimes it does not. The consequences of its rupture or perforation—the escape, I mean, of the contents of the bowel, and the supervention of intense and uncontrollable peritonitis—I need not again dwell upon. But the ulcers may, and doubtless often do, *heal*; and the scars which they leave behind them are frequently to be seen. The ulcerated surface seems to clothe itself afresh, by degrees, with a new mucous membrane, which is thin, however, and adherent to the subjacent tissues, and does not slide over them when pressed between the finger and thumb, as the healthy portions of the coats of the bowel will slide upon each other. And in the place of the cicatrix there is usually to be seen a slight amount of puckering, and a number of little wrinkles or lines, radiating from a common centre. According to Rokitsanski, with whose opinion Dr. Jenner's concurs, the formation of these cicatrices never leads to any diminution of the calibre of the bowel.

But it is plain, and most worthy of consideration, that the existence of these ulcers is likely to prolong the illness of the patient after the fever itself has ended; to protract his convalescence; to hinder his recovery; and even to endanger his life,

though he may seem to be getting well, by causing hæmorrhage, or perforation of the bowel.

Among numerous minuter points of difference between typhus and typhoid fever, observed and recorded by Dr. Jenner, there are yet two which demand mention in the sketch which I am now giving you. In typhoid fever that facile separation of the pia mater and arachnoid from the convolutions of the brain is seldom noticed, which I told you was common in typhus. Again, ulceration of the pharynx was discovered in one-third of Dr. Jenner's fatal cases after typhoid—in no single instance after typhus fever.

The spleen, after death, in both these forms of fever, is very frequently found altered in size and texture: enlarged, of a dark colour, and of soft and sometimes almost rotten consistence.

LECTURE LXXXV.

Relapsing Fever. Causes of Fever. Exciting and Predisposing. Prophylaxis.

WE were occupied, yesterday, in tracing the characteristic and distinguishing features of the two great species of continued fever, *typhus* and *typhoid*, which are of most common occurrence in this country, and which contribute so largely to the general mortality of its inhabitants. There remains yet another species sufficiently interesting and frequent to require a brief description.

There was prevalent in Scotland, in 1843-44, for fourteen or fifteen months, an epidemic fever, characterized by the suddenness of its onset, its wide diffusion, its short duration, and its small mortality;—by its proneness to relapses, by the frequent occurrence of petechiæ, of something like black-vomit, and of yellowness of the skin;—by the absence of intestinal ulcers; and by profuse sweatings, whereby the fever seemed to be solved. The history of this epidemic has been given by Dr. Alison, by Dr. Henderson, by Dr. Cormack, and in great detail by Dr. Wardell. It was thought by these physicians, and by others who witnessed it, to have been a new and distinct pestilence. It was, in fact, what is now well known by the name of *relapsing fever*. Later research has established this to be, indeed, a *distinct*, but by no means a *new* form of fever. In the following paragraph Dr. Jenner traces for more than a century the existence of a disease having the peculiar symptoms and course of relapsing fever.

“Writing on the weather of 1741, Rutton says ‘there was frequently a fever, altogether without the malignity of the disease already described, of six or seven days’ duration, terminating in a critical sweat (as did the other also frequently); but in this fever the patients were subject to a relapse, even to a third or fourth time, and yet recovered.’ In 1800 and 1801 there was an epidemic in Ireland of a fever generally terminating on the fifth or seventh day by perspiration, and when that happened, very liable to recur. Barker and Cheyne’s Reports, and Dr. Welch’s book on Blood-letting, prove the existence of a similar fever in 1816, 1817, 1818, 1819, and 1820, in Ireland and Scotland: while Dr. Christison’s testimony goes to show the identity of the type of fever in the epidemic of 1826 with that described by Dr. Welch, and also the similarity of the fever in these epidemics to that prevalent in 1843 and 1847.”

Dr. Ormerod has given us a sketch of this kind of fever as it fell under his observation in 1847 in the wards of St. Bartholomew’s Hospital. The subjects of it were chiefly Irish persons newly arrived in London. It was remarkable for the occurrence, in the majority of instances of *sudamina*, or miliary vesicles: so that Dr. Ormerod speaks of it under the name of miliary fever.

Relapsing fever begins, for the most part, with sudden rigors, severe headache, heat and dryness of the skin, loss of appetite, and a very rapid pulse. The tongue is

covered with a thick, moist, whitish fur. Epigastric tenderness, nausea, and vomiting are common among the early symptoms. There is much aching pain of the limbs and joints. The functions of the bowels are not materially disturbed. In many cases yellowness of the skin occurs, amounting to jaundice, with vomiting of matters looking like coffee-grounds, and sometimes as black as ink. Now Dr. Jenner declares, and my own experience is in agreement with his, that he never saw jaundice in typhus or in typhoid fever. Circumscribed petechial spots—"minute hæmorrhagic points," never elevated, are observable upon the skin in a large proportion of patients in relapsing fever. About the fifth, seventh, or ninth day a copious perspiration breaks out, and is followed by a sinking of the pulse to its healthy rate of beating, or even below that, and by what seems rapid recovery. But from the fifth to the eighth day from this apparent convalescence, the primary symptoms return; run, perhaps, a shorter course than before; again terminate in sweating, and in a second convalescence, which is generally permanent. The relapse or repetition of the symptoms may, however, happen three, or even four times.

The rate of mortality in this species of fever is low: and death usually takes place, if at all, before the seventh day of the disease. In the fatal cases jaundice has been observed to be a frequent, but not a constant symptom: the surface becomes cold and livid, the pulse very feeble as well as very frequent, a low form of delirium arises, with drowsiness, which deepens into unconsciousness, and so life departs.

It is stated by Dr. Wardell that in pregnant women affected with this fever, abortion is sure to happen, whatever may be the period of gestation.

In relapsing fever, neither early and extreme frequency of the pulse, nor sudden and great variations in its rate of beating, are, of themselves, prognostic of danger. In this respect, therefore, it differs remarkably from both typhus and typhoid fever, in either of which a pulse of 130 or 140, and in the former of which rapid fluctuations of the pulse, always indicate great peril. In relapsing fever it may amount to 150, or even higher, and upon the breaking out of perspiration it may drop, in the course of two or three hours, to half that number of beats, without warranting any alarm for the patient's safety.

Among the many points of diversity which exist between the three species of fever that we have been considering, one striking and obvious difference is to be found in their respective *duration*. This is apparent even to the observation of the vulgar, who have thus drawn rude distinctions between different epidemics, before they were recognised or acknowledged by the scientific physician. They talk of the one-and-twenty-day fever (typhoid), and of the fourteen-day fever (typhus), according as the disorder "takes the turn" in three weeks, or in a fortnight. In like manner the relapsing fever was called in Ireland the five-day fever; although as it has its crisis most often on the seventh day, it might be termed more properly the seven-day fever. We should thus have the natural duration of the three fevers marked by periods of *weeks*.

Typhus fever appears to be much more common in the great towns of England and of Scotland than it is in Paris, where typhoid fever is the predominant, if it be not the only, form. Relapsing fever has prevailed to a very great extent in Ireland, whence it was probably imported into Great Britain.

The symptoms of all these three forms of fever vary also, *cæteris paribus*, according to the *season of the year*, and the *situation* of the patient: whether, I mean, he be surrounded with pure and cool air, or with a foul and hot atmosphere. In the colder months there is greater risk of inflammatory complications, and especially of pectoral affections: in the autumn we look more for diarrhœa or for dysenteric complaints, engrafting themselves on the disorder. Where the air is close and foul, the symptoms show a much greater tendency to the low or putrid type, and the deaths are more numerous, than where it is pure.

It is of great importance to hold correct notions as to the *exciting cause* of continued fever; respecting which there has been, and there still is, a perplexing contrariety of opinion among medical men. You are aware, from what has already been stated, that I consider the disorder to originate in an animal poison, and to be contagious; communicable, I mean, from one who is labouring under the complaint, to another who is not.

When the same disease attacks many persons in the same house or neighbourhood, at about the same time, the popular suspicion soon arises that the disease is catching. Yet you know that disorders may be widely prevalent without being contagious. Agues, for example, engendered by malaria; ordinary catarrhs and sore throats, produced by vicissitudes of the weather. When an epidemic malady affects large masses of the people suddenly and at once, it is presumably not contagious; at any rate it must have some other source besides contagion. When, on the contrary, it begins in a certain spot, and gradually spreads thence as from a centre, the presumption is in favour of its propagation from person to person. In investigating this subject, if we trace the fever among persons who have had intercourse with the sick, and more frequently in proportion as that intercourse has been close and continued; and if we find that other persons, living in the same place, and under precisely the same circumstances, except that they have had no known communication with the sick, do escape the fever; we have in these facts convincing evidence that the disease has been spread by such intercourse; in one word, that it is contagious.

Have we, then, facts of this kind? We have, in the amplest abundance.

We find, even in hospitals, where cleanliness and ventilation are prized and enforced, that fever attacks many of the persons who come most often and most intimately in contact with those already ill of that disease; chiefly the nurses, next the clinical assistants and the most assiduous of the students, and the medical officers; rarely the other patients, even in the same ward. The separation of a few feet, if due regard be had to ventilation, is sufficient to render the poison inoperative, by diluting and diffusing it in the surrounding purer atmosphere. Three of our nurses in the Middlesex Hospital have fallen ill of fever during the severe epidemic now prevailing (1838); and two of the three have died. It is only when our wards are unusually full of fever-patients that these disasters occur: but they happen very often indeed, constituting the rule rather than the exception, whenever many fever-patients are collected together: as in hospitals which are exclusively appropriated to their reception, or in the fever *wards* of certain general hospitals. In such places the effluvia which proceed from the bodies of the sick are, in spite of all care, the most abundant and the most concentrated.

Dr. Welch, in his account of fever as it occurred in Queensbury House, in Edinburgh, which was opened for the *sole* use of fever-patients during the prevalence of an epidemic in that city, in the years 1817, 1818, and 1819, has the following statement in point. "In this hospital, since it was opened (which was the year before the time when Dr. Welch was writing), my friends, Messrs. Stephenson and Christison, the matron, two apothecaries in succession, the shop-boy, washerwoman, and thirty-eight nurses, have been infected; and four of the nurses have died. With the exception of but two or three nurses, who have been but a short time in the hospital, I am now the only person who has *not* caught the disease, either here, or at the Infirmary, within the last eight or ten months."

I may quote a passage from Dr. Alison, in illustration of the same thing. He is speaking of a more recent epidemic, which occurred in Edinburgh in 1827 and 1828. He says: "During this epidemic, as well as in that of 1817-1819, many of the clerks and nurses employed in the Royal Infirmary have taken fever. Since November last, six of the clerks employed in the clinical wards only, four of those employed in the ordinary wards, and twenty-five nurses or servants have taken fever. All these persons had necessarily frequent and close intercourse with the fever patients in the house, having been employed more or less constantly in the fever wards, excepting only four of the servants. Of these four, two had been employed in the laundry where the linen from the fever wards was washed; one was a porter employed at the gate, who would of course have communication with the fever patients at their entrance or dismissal, as well as with their relations coming to visit them; and one was a nurse employed in the servants' ward, but who was in the habit of visiting the fever wards." Now mark the contrast. He adds, that, "in this very place and season, those of its inhabitants who have *not* had intercourse with fever patients have almost uniformly escaped the disease. Of the inhabitants of the *ground floor* of the house, (including patients in the lock-ward,) none but those already mentioned as having washed the linen from the fever wards, and the barber who shaved the heads of the fever patients, have taken the disease. Yet in the case of malaria" (to which

I must apprise you that many medical men of great authority ascribe the occurrence of continued fever "it is the ground floor of the house that is generally found the most dangerous. No one of the nurses, whose duty has confined them to the medical or surgical wards where no fever patients were admitted, has taken fever, with the single exception of the woman in the servants' ward above mentioned. And of the numerous *patients* in these ordinary wards, the only one who has taken the fever, within my knowledge, during the present year, was a patient in the men's general clinical ward, who lay in the bed next the door that communicates with the clinical fever ward. If there be *malaria* in this house, therefore, it would seem to restrict itself *in point of space*, as at Queensbury-House *in point of time*, to the immediate vicinity of fever patients." To understand this last remark you should know that, in ordinary years, the inmates of Queensbury-House escaped fever.

We have similar testimony nearer home; in this metropolis. "Every physician connected with the London Fever House, with one exception (writes Dr. Tweedie), has been attacked with fever; and three out of eight have died of it. Also the resident medical officers, matrons, porters, laundresses, domestic servants not connected with the wards, and every female who has performed the duties of nurse, have, one and all, invariably, been the subjects of fever. And to show that the disease is capable of being engendered by fomites, or clothes, the laundresses, whose duty it is to wash the patients' clothes, are so invariably attacked with fever, that few women will undertake the loathsome and disgusting office."

Now it is in vain to attempt to escape from this kind of evidence, by saying that the situation of the Fever Hospital is infected with some local miasm; for the inmates of the Small-pox Hospital, which is immediately adjacent to it, are not affected in this way with continued fever, but remarkably exempt from it, as Dr. Gregory testifies.¹

Evidence of a somewhat different kind, but leading to the same conclusion, is to be found in the fact, that when persons, having the fever upon them, are transferred to some distant spot that was previously free from fever, they frequently form centres from which the disease begins, thenceforward, to spread. It is imparted in this way, even in the country, from family to family, and from village to village.

I was summoned home from Edinburgh on account of my mother's serious illness with continued fever. She was living in a village where there was little or no fever prevailing. While she was recovering my sister took the disease, and had it severely. It had evidently been introduced into the house by a man-servant, whose family lived in a neighbouring village. This family had the disease raging in their house, and he was in the habit of going thither occasionally, and always of sending his linen to be washed there. He first, in our house, had the disorder, then two of the maid-servants, and next my mother.

The cook of Trinity College, Cambridge, living in a street called the Petty Cury, had a daughter in London who fell ill with continued fever, and who insisted upon going home. At that time there probably was no case of fever in Cambridge: certainly none in the Petty Cury, as Dr. Haviland (who gave me this account) satisfied himself by inquiry. The girl was very ill indeed after she reached her father's house; but she ultimately recovered. Every inhabitant of that house, except an old, seasoned nurse, became affected with the fever; and three or four of them died. But no fever existed in the other houses of the same street. When one of the sick persons was convalescent, it was thought that her recovery might be accelerated if she were put into a lodging at Trumpington, a small village two or three miles from Cambridge, in which there certainly was then no fever. Here she and the old nurse were waited on by a servant belonging to the Trumpington House. That servant soon sickened of the fever, and was sent to Addenbrook's Hospital, where she died.

Take one more instance to the same effect, related by Dr. Alison. "Some years ago, at a time when there was no great number of fever cases in Edinburgh, I met with a case in the son of a shoemaker, who was lying in a room in which his father and two apprentices were at work. I could not prevail upon the father to remove his son to the hospital, although I stated the danger of the apprentices being affected. Within two or three weeks after, I found that the two apprentices were lying ill of

¹ Since this Lecture was first delivered, both these hospitals have been removed to new situations.

fever in their own houses: one of them two hundred yards, the other half a mile distant from the workshop, and widely distant from each other. These young men likewise lay at home during the fever; and each of their cases was speedily followed by a succession of others in the inhabitants of the rooms which they occupied, and of those immediately adjoining, who had never been at the workshop. In one of these houses seven, and in the other twelve, were thus affected. Now on the supposition of the fever being contagious, all this was to be expected, and all corresponded to the predictions which were hazarded on that belief. But on the supposition of such succession of fever cases depending on miasmata, there must have been at least two, more probably three, separate and accidentally concurring miasmata to explain the phenomena here observed; one at the workshop, and one at each of the houses of the apprentices; and there must have been this extraordinary coincidence that at each of these last the malaria sprung up just at a time when a patient was lying ill there of fever, which he had apparently contracted elsewhere. Further, the three houses in which these successions of fever cases were observed, are in situations very different from one another; and all of them have been, to my knowledge, perfectly free from fever for years together, both before and since that time, notwithstanding that fever has been much more generally prevalent, and that they have been inhabited by successive families. What probability is there (continues Dr. Alison) that three separate miasmata should have arisen in these three houses, just at the time when their presence was required in each to produce an effect which had been foretold as the consequence of another cause undeniably operating on all?"

If we contrast facts such as I have been advancing, with other cases, in which all the circumstances appear to have been precisely the same, *except* the presence of the alleged cause of the disease—making our observations always upon as large a scale as possible—we approach, as nearly as the subject will admit of, to a demonstrative proof that continued fever spreads by contagion.

The reports which were made by the accredited physicians, to a Committee of the House of Commons, respecting epidemic fever in Ireland, contain abundant and valuable evidence on this point also. Dr. Cheyne states that the farmers and householders in some parts of Wicklow, who would not harbour or admit into their houses strolling persons, nor go to wakes or funerals, remained free from the disease. In Ballytore a committee was formed of persons who took pains to instruct the inhabitants as to the precautions to be observed against infection: such as refusing admission to wandering beggars, absenting themselves from wakes and other assemblies; and even, under certain circumstances, from places of worship. These precautions were so effectual that not a case of fever occurred. Four villages in the neighbourhood of Lismore are stated by Dr. Barker to have been preserved from the fever, chiefly by the exertions of some Roman Catholic clergymen, who persuaded the inhabitants to avoid all communication with Lismore, and with another town in its vicinity, where the fever was rife.

It was observed also that bodies of persons collected together, and fenced about by barriers which precluded intercourse between them and places infected with the fever, remained exempt from it; children in charity schools, soldiers in barracks, and even prisoners in jails. In the same parliamentary report you may see a letter from Dr. McDonald, who had established a fever hospital at Belfast, which hospital alone, at one period, contained 190 cases of the disease. Very near the hospital was a school, containing 700 or 800 young persons; a poorhouse with 300 inmates; and a barrack with 1000 soldiers. These places were never more free from fever than at that time.

Facts to the same purpose abound in the medical reports of the army and navy. Those of the navy are especially valuable and instructive in this matter, because the whole of the circumstances in which the patients are placed come under the certain and immediate cognizance of the medical officers superintending them. I cannot go into particulars here, but must content myself with referring you to the writings of Dr. Lind, Sir Gilbert Blane, and Dr. Trotter. You will there find that ships which had, for a great length of time, been quite free from fever, have had that disease spread rapidly from one individual, recently imported, so as to affect almost all the crew. This was often the case when raw recruits were drafted from the receiving ships. It appears, from reports made to Dr. Trotter by different naval surgeons, and

published in his *Medicina Nautica*, that the fever was conveyed to a great number of vessels forming the Channel Fleet, from the receiving ship called the *Cambridge*.

It is, moreover, found, that when persons ill of fever are taken away from their own close and crowded houses, and when means of purification are employed, the fever ceases to spread in those houses. This well-ascertained fact it is which gives to fever hospitals their greatest, nay almost their only value. They would otherwise, as we have already seen, be detrimental or dangerous to all concerned with them, by concentrating the poison that produces the fever; without equivalent benefit. As it is, they cause, indeed, a certain amount of disease and of death; but by affording opportunities for clearing an infected neighbourhood of the seeds of the fever, and by so preventing its diffusion among a large and healthy community, they save many more lives than they sacrifice.

You may be surprised that I should appear to labour this point; and should take so much pains to prove what may seem to you, as I confess it seems to me, to be an undeniable proposition. But I do so because many have denied, and do still deny it; and plausible reasons are given, by men of name and character, for discarding altogether the notion of continued fever being propagated by contagion. Some even, who have begun by expressing their belief that the disorder was contagious, have ended by becoming strong, aye, violent anti-contagionists. The late Dr. Armstrong was one of these; and there are living men, of high and deserved repute, both in this country and abroad, who hold what I cannot help thinking erroneous — and if erroneous, then manifestly dangerous — opinions on the subject. Chomel informs us that not one in a hundred of the profession in Paris believes that typhoid fever is a communicable disease. Upon a subject so important it is right that you should be furnished with data for forming a correct and settled judgment. But I scarcely expect that the facts I have now brought forward will carry the same conviction to you all; for I agree with Dr. Christison in believing that the discrepancy which exists upon this, as upon some other controverted questions, depends, in part, upon the different structure of men's minds, and their peculiar habits of thought. Most of the anti-contagionists whom I have known have belonged to that party in this country which advocates what are called liberal opinions in politics and in religion. If this should prove to be generally true, it must be regarded as a curious psychological fact.

I have laid before you some of the positive evidence which goes to prove the contagiousness of continued fever. You may naturally ask, and it is but fair that I should tell you, what are the arguments on the other side of the question.

First, then, it is asserted that continued fever cannot be contagious, because some, nay many persons, who *have* intercourse with the sick, do not contract the disease.

But the force of this reasoning is completely broken by the well-known fact that, in respect of diseases which are on all hands acknowledged to be contagious, and which are even propagable by inoculation, small-pox for example, the same kind of exemption notoriously happens. Some of those who so escape may have had the fever before; and have thereby become less capable of being re-infected by the poison. I believe it to be uncommon for a person to have the same species of continued fever a second time, unless he is exposed to the contagious matter in a very concentrated state, or for a long time together. Some may, by original peculiarity of constitution, be proof against its power; but probably in most cases, the immunity arises from the circumstance that the person has been fortunate enough, or careful enough, to escape imbibing an effective dose of the poison. You may breathe, for a good while, without much hazard, an atmosphere but faintly imbued with the contagious effluvia; and you may, with somewhat more of hazard, breathe, for a short time, air which is strongly tainted by them, and yet go free.

Allowance must also be made, in some cases, for the effect of *habit* in fortifying the system against contagion. Persons who are much and often exposed to these effluvia, are thereby *seasoned*, in some degree, to the noxious atmosphere; just as drunkards and opium eaters become at length impassive under such a dose of their customary stimulus as would intoxicate or stupify a novice. Upon this principle has been explained the comparative immunity from contagious diseases, (under like circumstances of exposure,) of medical practitioners, and nurses; of the keepers of filthy lodging-houses, while the new-coming inmates suffer; and even of prisoners,

who, without having had the disease themselves, may nevertheless carry forth and communicate the infection: as is said to have happened at the celebrated "black assizes" in Oxford; and again at the Old Bailey in the year 1750.

This argument, that the fever cannot be contagious because many of those who come near the sick are not affected with it, has been happily ridiculed by comparing an epidemic to a battle. A man might say, "I was in the battle of Waterloo, and saw many men around me fall down, and die, and it was said that they were struck down by musket balls; but I know better than that, for I was there all the while, and so were many of my friends, and we never were hit by any musket balls. Musket balls, therefore, could not have been the cause of the deaths we witnessed." And if, like the matter of contagion, they were not palpable to the senses, such a person might go on to affirm that no proof existed of there being any such things as musket balls.

It must not be forgotten that this same argument, whatever may be its validity, is equally potent against any other general cause: against local miasms; against an undefined something in the air.

Again, the disorder does not spread, say they, in the houses of the rich. But why should it not do so, if it proceed from any cause which strict attention to cleanliness and ventilation does not disarm? The fact, when rightly considered, is a strong circumstance in favour of the theory of contagion.

But then the disorder often occurs when we can trace no contagion: and the full answer to this argument is to be found in the fact that the same difficulty applies to diseases which are not only confessedly contagious, but which are believed to have, now, no other source than contagion; even, as I showed you before, to small-pox. All that the argument can amount to, is a presumption that the distemper may sometimes originate independently of contagion. A person may be exposed to the agency of the contagious matter quite unconsciously, by coming into contact with fomites, or by approaching another person who is just convalescent from the disease. A nobleman died here, in the prime of life, last year, of scarlet fever. The story goes that he had just come to town, and was dining out, and by his side sat a young lady who had just recovered from that complaint; and that from her he unwittingly received it. A lady was attacked with small-pox; and pains were taken to discover how and where she could have caught it: at length it was ascertained that, some days before, she had sat in a carriage, while the post-horses were changed, at an inn-door, near the open window of a room in which a person ill of that disorder was lying. In such a place as this there are a thousand unsuspected ways in which contagion may be disseminated. It may lurk in a hackney coach; you may catch the complaint from your neighbour in an omnibus, at a theatre, or a concert, or at church; your linen may be impregnated with the subtle poison in the house of your laundress; or your coat may convey it from the workshop of your tailor. So that, when continued fever occurs, it is very difficult indeed to be *sure* that it has not arisen from contagion; and it becomes a very interesting question whether the disease ever proceeds from any other cause. It is, however, of primary importance to determine whether it be, or be not, communicable. By our belief in this matter the lives of our neighbours and clients may be saved, or lost. Even if we *doubt* about the contagiousness of the disease, we are bound to *act* as if we had no doubt upon the subject; and I would admonish you (although that is a lower and poorer motive) that your own reputation and success may be endangered by mistakes in this very thing. I have been told of one instance, which may serve as a warning. A lady came from the country to London, to see a sister, who was ill of fever. She asked the medical attendant if there was any danger of infection. He happened to be a staunch non-contagionist; and he said "no danger whatever." Upon the faith of that assurance, the lady resolved to sit up with, and to nurse her sister; but she fell sick herself of the disease, and died. I believe this did not shake the medical man's opinion. He attributed the mischance to some local miasm. But he could not persuade the lady's friends of this. They maintained that her death lay at his door; and whether they were right or wrong, the affair was so much talked of, and was so injurious to him, that he was obliged to leave that part of the town, and to seek for practice elsewhere.

Many sporadic cases occur of febrile disorder, which do not belong to the category of continued fevers, and yet are liable to be confounded with them. All the phleg-

masiæ are attended with pyrexia, and the local inflammation may be slight, or very obscurely marked, and easily overlooked; but the febrile symptoms are much the same as those which constitute the more *inflammatory* forms of typhoid fever. In like manner severe bodily injuries, compound fractures for example, sometimes give rise to constitutional symptoms precisely resembling the most prominent phenomena of the later stages of typhus fever. Excluding all such spurious resemblances of the genuine disease, I confess my own opinion to be, that continued fever, like small-pox and measles, originates, in all cases, from a specific poison. With respect to all these disorders, I conceive that, in every large community, there is constantly kept up a sufficient stock of contagious matter, to act as a sort of leaven, whenever circumstances favourable to the development of the disease as an epidemic, may chance to arise.

Continued fever has been ascribed, by those who deny its origin in contagion, to certain other causes; some of which demand attention, not merely on account of the interest that belongs to the whole inquiry, but also because they really are important agents in the extension of the disease.

First, then, it was, and is, a common belief, that continued fever may be *generated* by the effluvia constantly proceeding from the human body, even when healthy, if these effluvia are accumulated and condensed by the crowding together of many persons in close, dirty, and ill-ventilated places. It is unquestionable that, when once introduced, the disease spreads, under such circumstances, with fearful rapidity; but the point at issue is, whether it be ever so caused *de novo*. I must refer you, for good evidence that it is not so engendered, to Dr. Bancroft's book on the yellow fever. He shows that typhus fever does not spring up in places where it could scarcely fail to appear if that theory were true. He instances the natives of the Arctic regions, who, in order to shelter themselves against the extreme cold of their climate, live during the greater part of the year in close subterraneous dwellings, from which the fresh air is studiously excluded, and of which the atmosphere becomes so offensively foul as to be scarcely endurable by a stranger; yet continued fever is not known among them. A similar exemption from that disease is observed within the tropics, in the African slave ships, where "the poor wretches are crowded together below the deck, as close as they can possibly lie, in a sultry climate, barred down with iron, to prevent insurrection." Although many of them die from suffocation, and from fluxes, yet Dr. Trotter, who was himself, at one time, surgeon to a slave ship, declares that "contagious fevers are not their diseases." Dr. Bancroft quotes also a narrative of the sufferings of 193 Europeans, who, during the time of the first French revolution, were "deported" to Cayenne, in the *Decade* frigate. They were crowded, and even squeezed together, in so small a space, and for so long a time, that the sentinels, who were placed at the hatchways to guard them, and who were thus exposed to the hot and fetid air which came from their hole of confinement, demanded that their period of offensive duty might be shortened. Yet none of these miserable persons perished, nor did fever, properly so called, arise among them. Neither did that distemper present itself in any of the survivors of the black hole at Calcutta; the frightful account of which, by one of those survivors, Mr. Howell, is abstracted in an appendix to Dr. Bancroft's work.

Fever used to infest our English jails; but that it was always imported, and never engendered there by filth and defective ventilation, and by the accumulation of human effluvia, may be concluded from the fact that the benevolent Howard, when he visited the prisons on the continent, found, to his great surprise, that they were free from fever, although they were no less close, crowded, and impure than our own. He brings the result of his observations and inquiries concerning the cause of the jail-fever, to this pointed conclusion:—"If it were asked," says he, "what is the cause of the jail-fever, it would in general be readily replied, the want of fresh air and cleanliness; but as I have found in some prisons abroad, cells and dungeons as offensive and dirty as any I have observed in this country, where, however, this distemper was unknown, I am obliged to look out for some *additional cause* for its production"—which additional cause can be no other than the contagious poison emanating from the bodies of those who have the fever. It is true that fever is most frequently met with, and most rapidly propagated, where men are crowded together, in jails, or in close and ill ventilated places; but this affords no reason for supposing that it is ever

generated there, any more (to use a homely illustration of Dr. Bancroft's) than the general prevalence of lice and other parasitic vermin in such places, proves that these vermin are generated by filth, by pent-up human effluvia, and by want of ventilation, instead of being merely fostered thereby.

Again, continued fever has been attributed, with great confidence, to a vitiated state of the air, from the putrefaction of dead animal and vegetable substances. Dr. Bancroft deals with and demolishes this error also; showing that neither the putrid atmosphere of dissecting-rooms (respecting which *you* must have some personal experience), nor the noisome effluvia from full and ill-conducted burial-grounds, nor those to which tallow-chandlers, soap-boilers, glue and cat-gut makers, and the melters of whale-blubber, are exposed, nor the foul air of sewers and privies, have ever been known to produce anything like continued fever. In some parts of Essex, near the coast, where the farmers are in the habit of manuring their fields with shoals of sprats, I have seen large tracts covered with these fish in a state of putrefaction. The stench they occasion is horrible; but no disease results. Dr. Chisholm, in a paper to which I can only refer, but which I would recommend you to look at, in the sixth volume of the *Edinburgh Medical and Surgical Journal*, brings forward other and very satisfactory instances, to the same purpose: from a bone manufactory, near Bitton, in Gloucestershire; from an establishment (now relinquished) on the banks of the Avon, for converting the flesh of dead animals into adipocire; from manufactories for refining sugar, where the blood of slaughtered animals, obtained from butchers, is kept for that use; from the leather-dressing business;—all tending, I say, to the conclusion, that air, contaminated by the decomposition of animal substances, is not necessarily even noxious to life; still less productive of that specific disease which we are now considering. The old belief, therefore, was unfounded, that the exhalations from the dead and putrefying bodies of men and horses, lying unburied on the field of battle, are sufficient and likely to produce a pestilential fever. Many instances to the contrary are on record: one, of an early date, is thus stated by *Diemerbroeck*:—"Anno 1642, in agro Juliacensi maxima strages facta est, et ad minimum 8000 militum occisi fuerunt, præter majorem adhuc famulorum, rusticorum, aurigarum, puerorum et mulierum numerum, atque equorum copiam innumerabilem: corpora inhumata sub dio computruerunt, nulla tamen pestis insecuta est."

Mind, I neither deny nor doubt that filth, foul air, and the gaseous products of animal and vegetable decomposition, are things hurtful to health; or that they are capable, especially when intense and concentrated, of causing serious disease, and even death. Every now and then some startling proof of this noxious power is forced upon our notice. I well remember the stir occasioned by the sudden outbreak of a violent disorder among the boys in a large school at Clapham about 20 years ago. Nearly a score of them were all at once attacked with most alarming symptoms, and two of them died, in consequence of the opening of an old cess-pool behind the house, and the distribution of its foul contents over a garden adjoining their play-ground. The complaint thus produced was not, however, continued fever, but a sort of cholera. Very recently a formidable endemic malady, arising, there is reason to believe, from a similar cause, broke out in the neighbourhood of the cloisters of Westminster Abbey: and a panic for some days pervaded this end of the town, respecting the "Westminster Fever." The distemper proved fatal in four or five instances. But, although it was attended with febrile symptoms, it was totally unlike (at least the case of it which I saw, and those of which I heard the most, were totally unlike) any form of continued fever that, during no very short or scanty experience, has ever fallen under my observation. The disorder was such as certain poisons are known to excite in the animal economy. Within the space of eleven days it affected upwards of thirty persons; following very exactly, in its course, the line of a foul and neglected sewer, which communicated by direct openings with several, and was in close proximity to nearly all, of the houses in which the disease occurred. It did not spread further or afterwards. What I do doubt—though I would not venture absolutely to deny—is, that genuine continued fever—that typhus, typhoid, or relapsing fever—has ever such an origin. I agree with Dr. Guy—whose interesting report upon the health of nightmen, scavengers, and dustmen is well worth your perusal in connexion with this subject—I agree with him in believing that "filth is rather the *nurse* than the *parent* of fever:" but I am not persuaded of the correctness of his final conclusion, that, "in

extreme cases, fever may be bred of filth." The sanitary measures which are now in contemplation by the government are deserving of all praise and help. To cleanse, to drain, to ventilate all parts, and especially the poorer and most populous parts, of our cities and towns, is to promote their general salubrity, and to fortify them, as well as human prudence can fortify them, against the ravages of pestilential disease, which are far greater than even those of war. But, in my judgment, it is wiser and safer to advocate these measures, not upon the disputed opinion that epidemic fever may be engendered by the impurities which they are intended to banish, but upon the unquestionable fact that fever is fostered and spread through those impurities. The specific exciting cause of continued fever cannot perhaps be utterly expelled or precluded; but when present in a community, it may be rendered comparatively harmless by taking away the main conditions of its morbidiferous efficacy, and of its faculty of propagation.

It has been said that fever is produced by some unknown condition of the air, imperceptible by our senses, but distinct from contagion. I believe this is a very popular notion; but it is perfectly gratuitous and untenable, and inconsistent with observed facts. You may have fever raging in certain parts of a town, and yet the parts in the immediate vicinity of these be quite exempt from it. Now this could hardly be, if there were some general property diffused through the common atmosphere capable of engendering continued fever; and, as I stated before, this notion is severely pressed by one of the arguments which the non-contagionists themselves are fond of employing. If the disease depend upon contagion, some persons in the community may come less near the sick, or imbibe a less dose of the contagious poison, than others, and so escape; but if the cause of fever were spread abroad throughout the whole atmosphere, *all* must be exposed to its influence, and few, we may suppose, could avoid suffering from its operation.

Exposure to cold is another cause to which fever has been sometimes attributed. But this is an agency so widely prevalent, that if it alone could excite fever, that complaint would be far more general than it really is, and we should be able to trace it oftener and more distinctly than we can, to the alleged cause. That cold, by its debilitating effect, may predispose the body to be affected by the contagion of fever, I well believe: and the same remark is applicable to another cause that has been assigned; namely, deficiency of nourishment. Dr. Alison, in his admirable essay *On the Management of the Poor of Scotland*, has clearly proved that the prevalence of contagious fever amongst the lower orders is always in direct proportion to their state of physical destitution. The association of pestilence with famine is proverbial. But we do not find that continued fever is ever created by the mere want of nutriment. In persons who have sought to starve themselves to death—among sailors who have of necessity been kept upon very short allowances of food—in cases of isolation by snow storms, or by the accidental closure of a mine—we find, indeed, that *disease* is produced by the privation of nourishment; but it is not continued fever. The condition into which the sufferers are brought is more like scurvy. So that although the want of sufficient aliment may be, and doubtless is, a powerful auxiliary in promoting the effect of the contagious poison, there is no ground for supposing that it ever primarily or solely occasions fever.

In fact, all the circumstances which I have now been considering act as *predisposing* causes. They render the human body an easier prey to the real *exciting* cause, which is a specific animal poison. You will remark that they are all *debilitating* circumstances; and where several of them co-exist, their joint influence in subduing the system, and bringing it into subjection to the contagion, is very great. For the same reason, depression of spirits, however produced, has a strong predisposing effect; as strong, perhaps, as any other single cause. Of this I have seen, if I mistake not, some remarkable examples. Upon this principle we may explain the fact, that continued fever is especially apt to attack those of the lower classes who have recently come to reside in the metropolis; who are often living anxiously, and with persons to whom they were not previously known. We have had numerous opportunities, in the hospital, of noticing this curious circumstance: and it is mentioned by almost all the French writers on fever. To the same principle also we must attribute the tendency to fall down in fever, observed in young soldiers and sailors. You will find statements to that effect in Dr. Trotter's works, and in those

of Dr. Lind and of Sir Gilbert Blane. When fever appears in a ship, the raw sailors are always the soonest attacked by it; and it is the same with the recruits in the land service. In a defeated, dispirited, or retreating army, its ravages are often frightful. Here we have combined, fatigue, a deficiency of wholesome food, and mental depression.

However paradoxical the assertion may seem, a predisposing cause may even be applied, and operate, *after* the exposure to the exciting cause — and so render the latter effective when it might not, otherwise, have been so. Dr. Russell observed the plague sometimes to “hang ambiguously” about persons for several days. In this state, an overheated bath, or a sudden impression of fear, especially *fear of the disease*, has roused the lurking poison into activity. It is a suggestion of Dr. Henry’s that atmospheric variations may call into action contagious poisons already admitted into the system, but not yet manifested by the usual phenomena: and, operating thus over a wide space, and upon numbers at once, may occasion those sudden and violent outbursts of epidemic disease, of which numerous examples are on record.

You must, I think, perceive the importance of distinguishing between the one exciting cause and the many predisposing causes of fever. Both may be combated, with more or less prospect of success. Some of the latter are mostly beyond our absolute control. We cannot hope to prevent or remedy extensive destitution; nor to separate it effectually from its concomitants of filth and despondency of mind. But we may, by timely diligence, root out the specific contagion, or confine it within narrow bounds. When the sick can be at once removed from their crowded homes to a fever hospital, and their impure apartments ventilated, cleansed, and whitewashed, the disease may often be kept in check, if not entirely stopped; and the yet healthy persons of the infected district be preserved from its grasp. For, as I stated before, there is reason to believe that the poison, unless pent up, does not remain active at any great distance from the person from whom it proceeds; not even many yards, or feet. It is very rare, I apprehend, to meet with instances of the disease being communicated in the open air. It is almost always caught, if at all, in the interior of houses. It is extremely uncommon for it to extend from one bed to another in our general hospitals, where great attention is paid to cleanliness and ventilation. The noxious qualities of the poison are diminished, and at length destroyed, by its dilution with common air, just as those of other gaseous poisons are: and hence, in private houses, in the better ranks of society, where the rooms are spacious and airy, and proper precautions are taken, the disease hardly ever spreads.

What are those proper precautions? They are simple, and may be stated in very few words.

Where choice can be made, a large apartment should be selected for the sick person. Unless the weather be very hot, there should be a fire in the room, for it acts as a ventilator. The air of the chamber should be kept fresh by having a window, or a door (according to the weather) always open; or both window and door. Bed and window curtains, carpets, and all superfluous articles of furniture should be removed. Great diligence should be used in keeping the patient clean, by the requisite ablutions, and by frequently changing his sheets and his body linen; and these should be immersed at once in water; and all discharges from the sick person’s body should be instantly carried out of the room.

All unnecessary intercourse with the patient, by his family and friends, should, for his sake, as well as for theirs, be forbidden. As life advances, the susceptibility of the disease appears to diminish; for which reason the nurses and personal attendants of the patient should not be very young: and all who do approach the sick bed should take care to avoid, as much as possible, inhaling the patient’s breath, or the emanations which proceed from his person. Friends who visit the apartment at intervals only, should never enter it *fasting*.

And *in aid* of the simple measures I have just recommended, but by no means *instead* of them, you may, if you please, employ the chloride of lime, or the chloride of zinc, or the nitrate of lead, or freshly burned charcoal, which have been vaunted as “disinfecting” agents; though no conclusive evidence has yet been advanced of their possessing anything more than the very useful and convenient property of destroying noisome smells. People hang a bag of camphor round their necks, and think themselves safe against infection. The mental confidence which that expedient

is calculated to inspire, may perhaps afford some degree of protection : but camphor has, in reality, no prophylactic virtue : and all these artificial scents are objectionable, inasmuch as they tend to conceal offensive odours which might otherwise reveal the actual danger.

Most of what has now been delivered respecting the contagious nature of continued fever, was written and delivered while I yet conceived that there was but one species of that disorder. You may naturally desire to know whether the same contagious quality belongs to *all* the three species of fever which the progress of medical science has since compelled me to recognize — to the typhoid, the typhus, and the relapsing fever : and if so, whether these are all equally contagious : and again, whether they all spring from the same poison, or whether each is caused by its proper virus only.

I believe that they all are contagious : I believe that the contagious property is not equally intense in them all : and I believe that one species of fever cannot generate another, but that each is produced solely and exclusively by its like : that typhus always propagates typhus, and never typhoid or relapsing fever — and so of the rest.

Let us take the last of these propositions ; for the proof of it must include the proof of the first also.

Upon this point we are again indebted to Dr. Jenner for the most satisfactory evidence that has yet been collected. He noticed, as others have done, that whichever of the three species was, in its turn, prevalent in epidemic abundance, cases of the other two were intermixed ; and that these retained without change or modification their characteristic features. There were no transition forms ; nothing like graduation of one species into another. He also took pains, during the years 1847, 1848, and 1849, to track the in-patients of the Fever Hospital to their several homes ; and he found that where more than one fever patient came from the same family or the same house, they all presented the same species of fever. He thus traced 208 patients from 75 different sources of infection, with one exception only to the rule just stated : and this sole exception admitted of an explanation so reasonable, that it could scarcely be said to militate against the general inference.

You may read his evidence in full, in the 33rd volume of the *Medico-Chirurgical Transactions*.

Now this great truth attests conclusively the specific difference of the three diseases. It had suggested itself to other minds, but had never been so successfully worked out. Dr. Alison, in his description of the epidemic relapsing fever of 1833–34, says, “Patients with two kinds of fever, not to be clearly distinguished from one another in the early stage, are daily admitted ; and each of these forms of fever appears to be easily *communicated* in the hospital itself, to *convalescents from the other*.” Dr. Henderson, writing in the 61st volume of the *Edinburgh Medical and Surgical Journal* upon the same epidemic, states that in nine instances the same persons had exhibited the epidemic (or relapsing) form, *and* typhus, within a very short time. He concludes “that the two forms of fever do not acknowledge a common origin ; that they are not propagated indifferently from the same sources of infection ; that the one will not produce the other.”

In corroboration of the same conclusion, Dr. Bartlett adduces the remarkable, and otherwise inexplicable fact, “that for the long period of the last thirty or forty years, in the city of Paris, and throughout New England, where this subject has been most carefully studied, only one of these forms of disease has prevailed, to the entire and absolute exclusion of the others.”

This being so, the likelihood increases that continued fever never arises except from contagion. Also, since the same person may have each of these separate diseases, it will probably be found, as more exact observations multiply, that the cases in which the same person suffers the same fever twice, are not more numerous than those in which small-pox, measles, or scarlet fever repeat themselves. Dr. Jenner has never known the same individual to be affected twice with typhus fever. A second attack of the typhoid form I believe to be quite as rare. “It is universally acknowledged (says Dr. Henderson) among those who have had much to do with typhus, that an attack bestows immunity from the disease for a long time at least afterwards. I have myself seen no example of a repetition or recurrence of typhus during the

persistence of the same epidemic, and epidemics of typhus usually last between two and three years." He bears similar testimony in regard to the relapsing fever.

Of the three, typhus fever appears to be the most readily communicable from person to person. Dr. Jenner holds typhoid fever to be contagious, "but infinitely less so than typhus." The Scottish records of relapsing fever demonstrate its strong tendency to spread.

I shall speak of the treatment of continued fever when we next meet.

LECTURE LXXXVI.

Continued Fever, concluded. Treatment. Small-pox. Its essential symptoms. Distinction into discrete and confluent. Periods and modes in which it proves fatal.

THE treatment of continued fever has been, at all times, a stumbling-block to young practitioners; and a subject of dispute even among physicians who have built it upon their own experience. Before I attempt to trace out any plan, or to lay down any principles for your guidance, it may be useful to inquire how it happens that the practice in this disease has been so fluctuating and unsettled.

In the first place, then, it is very difficult to estimate the value and efficacy of any particular plan of treatment, and still more of any particular remedial substances, in this disease. Continued fever, of whatever species, like other disorders which run a definite course, and have no direct or necessary operation in spoiling the structure of vital organs, has a strong natural tendency to terminate in health. We see this tendency when the disease is left entirely to itself, and it equally exists when remedies are employed to regulate its course, or to abbreviate its duration. No one can doubt, who has had much experience in fever, that this tendency is sometimes thwarted by the *nimia cura medici*; and that patients get well in spite of the well-meant but mischievous interference of the Doctor. This tendency to recover is a constant source, therefore, of fallacy in our observations upon the behaviour of this disease under different plans of treatment; and upon the effects and utility of remedies. It leads us, too often, into the danger of ascribing to drugs what is really due to the workings of nature; of confounding antecedents and sequences with causes and effects; of counting recoveries as cures. And this danger is increased by the circumstance that continued fever, although it observes a certain definite course, is nevertheless liable, even when left altogether to itself, to sudden and remarkable changes in the symptoms, sometimes for the worse, and sometimes for the better; and often we cannot perceive any obvious reason for these fluctuations. But if this happen when no medicine is given, so also will it happen when the disease is submitted to treatment; and it requires more than a little care and discretion to avoid attributing the changes which so occur to the remedy which was last employed. For example, the abatement or cessation of *headache*, after a few days have elapsed, is a natural phenomenon; whereas an inexperienced or a careless person might easily persuade himself that it had yielded to his method of treatment, and that it was a favourable omen: neither of which conclusions would, however, be warranted by the circumstance upon which it was founded.

There is yet another source of difficulty connected with the subject. I have shown you that not only individual cases of fever, but different epidemics, vary much in their character; nay, that different epidemics may consist of diseases, which though heretofore accounted the same, are really and specifically distinct in kind; so that a plan of treatment which was well suited to one epidemic, may be improper and even hurtful if indiscriminately applied in another.

These considerations may serve in some measure to teach us how it has happened that so many *different*, and sometimes *opposite* remedies and modes of treatment have been recommended by different practitioners for the cure of continued fever. The distinctions established by Dr. Jenner, while they somewhat disturb our previous confidence in the teachings of past experience on this subject, will render all future experience more exact, and probably more uniform also.

The natural tendency to a termination in health was very plainly visible in the epidemic fever in Ireland, to which I have more than once referred; and which was apparently *relapsing* fever. The mortality among the patients who were placed in sheds upon straw, and left with very little medical care, and even without any great personal attention from others, was very small indeed. No one can form even an approximate judgment of this tendency, who has not seen the disease under several varieties of practice. Doubtless one rule which we derive from a clear perception of the same tendency is, that we should *not* interfere *unnecessarily*. *Δοκίμειν περὶ τὰ νοσήματα δυο* (says Hippocrates), *ωφελεῖεν, ἢ μὴ βλαπτειν*. Two objects are to be kept in view in the treatment of diseases: first, that we do the patient *good*; secondly, that *at least* we do him *no harm*. In all these exanthemata, he must be reckoned the safest and the best practitioner who knows when to abstain from acting, as well as when to act; in other words, who has learned when, and to what extent, the case may be left to the salutary processes of nature.

However, there is an opposite error to that of mischievous activity. The tendency to recovery which manifests itself under different modes of treatment, and even in spite of opposite modes, has induced, in some minds, a degree of scepticism as to the utility of any remedies, that may easily be carried too far. It does not follow, because the majority of patients under continued fever would at length emerge into health, although no remedial measures were employed, that the disease ought therefore to be abandoned to what Cullen calls the *vis medicatrix naturæ*. It is not quite correct to say, with the older pathologists, that the whole disorder is merely an effort of nature to throw off something noxious to the system, and *therefore* is not to be interfered with. The true view of the matter I apprehend to be that which a toxicologist might take. The disease is produced by a poison of which the injurious impression upon the animal economy at length ceases, or passes off, of itself; in the same manner, only more slowly, as the influence of a dose of opium will spontaneously pass away. But during the natural course of the fever, as in many other cases of poisoning, morbid processes are apt to be set up, which, if suffered to proceed unchecked, would inflict irreparable injury upon important organs, and which are fairly within the scope of curative management. Tendencies accompany, or conditions survive the fever, which remedial measures, opportunely and judiciously applied, avail to oppose and to control. Our object must be, when the fever is once established, to conduct it to a favourable close; to “obviate the tendency to death.” Upon this point I agree most entirely with Piteairn, who, being asked what he thought of a certain treatise on fevers, declared, “I do not like fever cures. You may *guide* a fever; you cannot *cure* it. What would you think of a pilot who attempted to quell a storm? either position is equally absurd. In the storm you steer the ship as well as you can; and in a fever you can only employ patience and judicious measures to meet the difficulties of the case.”

When some immediate change ensues in the symptoms or in the feelings of the patient upon the administration of remedies that are generally followed by sensible effects, we are warranted in ascribing the change to those remedies. But even here comes in the fallacy already noticed, arising from the sudden and *spontaneous* changes that are apt to occur in fever: and this fallacy is to be got over only by multiplying our observations.

After all, the best guide that you can have in determining upon the general principle of treatment in a given epidemic, or even in an individual case, is that which Dr. Alison has so ably enforced in his lectures and in his writings upon this subject. I mean the observed tendency to this or that mode of dying. The manner and circumstances of the deaths, are of more practical importance than of the recoveries.

After briefly passing in review some of the principal remedies that have been employed and recommended for this disease, I propose to sketch the plan which I am myself in the habit of pursuing in the management of fever patients.

It was once a favourite practice with physicians to attempt to *cut short* the fever at its outset: and the two expedients which were chiefly relied upon for that purpose were *emetics*, and the *cold affusion*. They have both of them, in this country, gone very much out of fashion. In truth, neither reason nor experience encourages us to look for such a result from such measures. If fever depend (as I believe it does) upon a poison in the blood, it is not to be dislodged by the act of vomiting, nor washed out by the forcible descent of cold water upon the skin: and in the few instances in which the one or the other of these remedies may have *seemed* to arrest a fever, or to check its progress, that effect has always occurred at the very commencement of the complaint: so that we cannot be sure (and the probability lies the other way) that these were really causes of fever at all, or that they would not have ceased even if nothing had been done for them. Perhaps emetics may, in the present day, be too much neglected. I have no notion of their *stopping* the fever; but when given early, especially if gastric disturbance be a prominent symptom, they are sometimes followed by a marked abatement of many morbid sensations. "It is astonishing," says the observant Sydenham, "how it happens that a vomit, which does not produce either a large or a morbid discharge from the stomach, should so materially relieve the nausea, restlessness, anxiety, and furred tongue of the patient."

The cold affusion is not more effectual in cutting fever short than the treatment by emetics; and it has this great disadvantage, that it fatigues and alarms the patient: and when the vital powers are naturally feeble, or are much depressed by the disease, the very shock of the affusion may be attended with injurious consequences.

A modification of this expedient is, however, often of great use in abating the morbid heat, and soothing the uneasy feelings of the patient. I mean the practice of cold or tepid *sponging* of the surface. This is one of the remedies which, when the symptoms appear to indicate it, deserves to be tried; and the propriety of continuing or of discontinuing it may be determined by a very simple test, namely, the feelings and wishes of the patient himself respecting it. Speaking generally, it is less eligible in that form of fever which we must henceforth call typhus, and it is chiefly adapted to the typhoid disease.

Great controversies have been maintained in regard to the effects of *blood-letting* in fever. They who hold that the fever consists in a general disturbance of the system, growing out of some local inflammation, and they especially who believe that continued fever is nothing else than inflammation of the brain and its membranes, would naturally seek to cure it by the remedies of inflammation. But although local inflammation, and even inflammation of the brain, is very apt to spring up in the course of continued fever, there is no reason for thinking that inflammation *any where* is *essential* to the fever; but very much reason for the opposite opinion. The active use of blood-letting has been in favour and out of favour, with the medical world, again and again: and this very circumstance would of itself make us doubt the propriety of its indiscriminate adoption.

The late Dr. Armstrong gave a strong and unfortunate impulse to the practice of free blood-letting in continued fever, by the publication of his well-known and ingenious treatise on the disease. I have no doubt that great mischief was done by that work. I may say so without scruple, since Dr. Armstrong is gone, and neither his feelings, nor his success, can be hurt by the expression of such an opinion; and I do so the rather, because it is well known here that Dr. Armstrong saw reason, as his experience increased, to qualify those views respecting the nature and management of fever, which his earlier observation of it in the country had led him to form. This change in his sentiments was probably justified and produced by a specific difference in the character of the fevers that he subsequently witnessed; but it does not appear in his book. You have heard me state already that whereas the fevers which occurred in London for some time previously to the year 1831 or 1832, not only bore, but sometimes even required, the abstraction of blood, in one way or another,—since that period, and especially since the epidemic cholera began to visit us, it has been necessary to abstain, whenever we could with safety, from taking blood at all: and still more necessary, even if we take away blood with one hand, to uphold the patient with the other; while, in the former period, wine and stimulants of all kinds seemed generally superfluous, if not pernicious. Typhoid fever I believe to have been predominant during my earlier, typhus during my later experience.

Dr. Robert Williams, of St. Thomas's Hospital, has shown, very clearly I think, in his excellent work on "Morbid Poisons," that the evidence against the efficacy and the safety of bleeding in continued fever—of bleeding largely, I mean, from the arm, far outweighs that in its favour: and I venture to advise you, as the result of all that I have seen of the disease in London and elsewhere, *not* to draw blood from a vein, even early, *merely* because the disease is or appears to be *fever*; not to order venæ-section unless there be some other manifest reason for it—unless, *i. e.*, the febrile symptoms run unusually high, or unless some local inflammation is unequivocally present: and, when you do bleed, do not take a drop of blood more than seems absolutely necessary to answer the desired end. Bleed your patient, therefore, if at all, in the upright posture.

Purgatives—What are we to say in general with respect to them? This, I believe—that the intestines should be cleared by an active aperient in the outset; and that laxatives should be continued if the bowels do not act every day without them. When however the vital power is much depressed, and when the symptoms indicate or threaten ulceration of the intestinal glands, purgatives certainly ought not to be pressed.

Much contrariety of opinion has prevailed also among practitioners, and does prevail, about the administration of *mercury* in this disorder. Without attempting to strike the balance between these conflicting judgments, it is my business and duty to state my own belief, to tell you what is the result of my own observation, upon this and other disputed points. I must repeat, then, that my practice has altered, in several particulars, within the last few years. In the fevers which I treated, or saw others treat, in London, prior to the appearance of the more recent epidemics, mercury, in one shape or another, was almost constantly prescribed; and a great number of the patients were brought, sooner or later, under the specific operation of that mineral: and in these patients (with one exception only, where the mercury appeared to do neither good nor harm) a *decided improvement* was almost immediately apparent upon the supervention of soreness of the mouth; and all such patients ultimately recovered. I am aware, however, and I wish you to be aware, of an alleged source of fallacy in this matter. The gums in that variety of fever to which I am at present referring, did not readily take on the mercurial action; and it *might be* (though such is not my own impression), it might be that the affection of the mouth by mercury was attributable to the mildness or to the cessation of the disease, rather than the cessation of the disease to the effects of the mercury upon the system: that the improvement was the cause, and not the consequence, of the mercurial action.

In the form of fever that is *now* epidemic (1838), I do not think mercury so proper. Last year the spotted (*i. e.* typhus) fever broke out in a patient of mine while he was in the hospital, and while his gums were sore. I found, upon inquiry at that time, that of twelve fever-patients who had been recently treated in the hospital, by my colleagues and myself, with mercurials in greater or less quantity, four had died, in all of whom the gums were affected: whereas, of sixteen others, who took no mercury, three only died; and of these three, one was pulseless at her admission, from uterine hæmorrhage, and the other two were so feeble and exhausted that they were scarcely able to swallow. I should give mercury therefore very cautiously, if at all, in fever that is marked by the mulberry rash.

Besides a careful enforcement of the antiphlogistic regimen, my own mode of treating continued fever is somewhat of this kind. I am always desirous that the patient's hair should be cut off. The mere removal of it is often attended with benefit; the headache and confusion of thought are relieved, and the patient is calmed. We can then also, with much greater convenience and effect, apply cold washes to the head. Patients sometimes demur to this shaving of their heads; but they generally consent if you explain to them that their hair will at length fall off, in consequence of the fever; and that the head, if on that account only, had better be shaved at once. The head and shoulders should be somewhat raised, and thin strips of linen, kept constantly wet with some cold lotion, should be constantly applied upon the forehead and scalp. It should be the business of one person to attend to this. You would be surprised at the rapidity with which the cloths sometimes dry.

Now with regard to this remedial measure you need not have any difficulty. It

will do good, and should be steadily employed, so long as it is *grateful to the feelings* of the patient; and it *will*, generally, be pleasant and agreeable to him so long as the head remains morbidly hot. If the temperature of the scalp be not above the natural standard, and especially if the cold application make him shivery or uneasy, and give him annoyance instead of comfort, then it must be at once discontinued.

If the patient suffered intense headache, and his face were flushed and the heat of the surface great, and he were wildly delirious, and his pulse were full and hard, I might perhaps deem it right to take blood from his arm, while he sat up. But even under these circumstances I should generally think it better to apply leeches to his temples, or behind his ears, or to remove a few ounces of blood from his neck by means of cupping-glasses, and at the same time to apply assiduously the cold lotion. The combination of headache with delirium warrants the suspicion that inflammatory mischief may be going on in the brain. Dr. Jenner observes, of all these species of fever, that "after the patient becomes delirious he never complains of headache, and rarely admits its existence even when questioned concerning it; while in cases of intracranial inflammation headache is constantly and even loudly complained of, after delirium has commenced."

In the outset of the disease, and while its species may as yet be uncertain, if the bowels have not been already purged by nature or by art, it will be right to give three or four grains of calomel at once, and to follow up this dose by a senna draught. After that, in the earlier period of the fever, especially if the alvine discharges are scanty, dark-coloured, or otherwise of unnatural appearance, a couple of grains of calomel, or four or five grains of the *hydrargyrum cum cretâ*, may very properly be prescribed, in pills, three or four times a day. And the common saline draught will generally be useful and refreshing to the patient; who may be allowed to drink toast and water also, or barley-water, as often as he wishes. As the disorder goes on, if the rose coloured spots declare it to be of the typhoid species, and if diarrhœa arise, the state of the abdomen should be carefully investigated; and when much tenderness is found to exist in the caecal region, with gurgling perhaps felt under gentle pressure with the hand, a few leeches may be applied over the tender spot, and their bites covered with a light poultice: and should the diarrhœa persist, or become profuse, a certain quantity of Dover's powder, or of the extract of poppy, should be added to the *hydrargyrum cum cretâ*.

But if the fever should prove to be typhus, and to exhibit a strong and early tendency to depression of the vital power, with a signal loss of muscular strength, a confused and dusky countenance, a mottled state of the skin, simulating the eruption of measles, a dry dark-brown tongue, and a feeble pulse—under these circumstances you must begin very early to give the patient a full allowance of good beef tea; and if the symptoms of prostration become more pronounced, you may add ammonia in full doses, Hoffman's æther, or what is much the best of all, wine: and you must omit the mercury.

Under this kind of management the patients will often go on, in a doubtful state, for some days, and at length begin to recover. Many of them, in both species of fever, but especially in typhus, sleep heavily, as the disorder passes slowly off.

There is one point in the treatment of fever, of exceeding importance, and of some nicety: I mean the use of *opiates*. When they are given inopportunistly, they are apt to puzzle and perplex the case. You do not know how much of the disposition to coma is owing to the disease, and how much is the consequence of the remedy. Again, you may easily *augment* the natural tendency to coma, and lull your patient into a fatal stupor. But, when judiciously administered, opium will often save a patient who would inevitably sink without it.

It is in that form of fever which the French call the *fièvre ataxique*,—when the patient is affected with delirium, restlessness, wakefulness, and spasm, and the disturbance of the nervous system outruns the disturbance of the sanguiferous system,—that opium is so beneficial. The condition of the patient resembles that of a person in *delirium tremens*. It is said that these symptoms occur most commonly among patients in those ranks of life that are above the lowest rank; and it probably is so: but they are apt to take place in any patients, high or low, rich or poor, who have had the mind overwrought, and the nervous system unstrung, whether by dissipation and intemperance, or by anxiety of any kind. Sydenham was quite aware of

the existence of this particular set of symptoms, and of the remedy for them. Of all these symptoms, *sleeplessness* is the most urgent. Dr. Grattan and Dr. Latham have both written in praise of the same opiate treatment, under such circumstances, as was recommended by Sydenham. Dr. Grattan observes, with great truth, that two or three nights spent in restless delirium are followed by the worst consequences; and that patients who pass *three* nights in succession in that way, almost invariably die. If the symptoms be well marked, the best mode of proceeding is to give a tolerably full dose of opium in the evening; one-third of a grain of acetate of morphia is a common prescription with me. The amendment of the patient, on the following day, is often very striking. Unless the same symptoms recur, it is better, I think, not to *repeat* the anodyne. But, as Dr. Latham cautions us, "there are cases, where the indications for the employment of opium are *doubtful*. Wild delirium, and long wakefulness, and a circulation weak and fluttering, seem to call for a considerable dose of opium. Yet, withal, there is a certain jerk in the pulse, so that we cannot help *suspecting* that the blood-vessels have something to do with the sensorial excitement. Under such circumstances, I have certainly seen (says he) twenty minims of laudanum produce tranquil sleep, from which the patient has awoke quite a new man. But I have also seen the same quantity produce a fatal coma, from which he has never been roused. Now (continues Dr. Latham) since it is a fearful thing to strike a heavy blow in the dark, where the alternative is of such magnitude, it is the safest and best method to administer a small dose, at intervals of an hour or two: so as to stop short of actual mischief at the first glimpse of its approach, or to be led, by a plain earnest of benefit, to push the remedy to its full and consummate effect. Many doses may be required for this purpose; but we shall see, after the first or second, whether to go on or to desist."

When, as is sometimes the case, the stress of the disorder falls upon the thorax, and there is much dyspnoea, with the sounds that denote inflammation of the bronchial membrane, or of the pulmonary substance, leeches or cupping-glasses may be applied to the chest; and, in milder cases, a blister, or a mustard cataplasm.

These remedies—cold to the shaven head; the local abstraction of blood wherever there happens to arise unequivocal evidence of local inflammation; an active purge at first, and mild aperients afterwards, if the bowels are confined or sluggish; moderate astringents, if there be much or urgent diarrhoea, a few grains of Dover's powder, for example, or of the extract of catechu; opium in a more efficient dose, when the nervous symptoms are prominent, particularly sleepless delirium and restlessness; in certain cases small and repeated doses of some preparation of mercury; and in certain cases, *early* support by animal broths, and even by wine—these remedies, adapted to the particular circumstances of individual patients, form the staple of the treatment of continued fever, according to the best of my judgment and experience.

After what has been said, I need scarcely again admonish you to study carefully, not merely the symptoms of any particular case to which you may be called, but the general character of the fevers that are at the same time prevalent, and the manner of dying in the fatal cases. If you find that they who die, die chiefly in the way of asthenia, that will be a strong reason for caution with respect to the removal of blood, and for the early employment of beef-tea, and other means of support. In the form of fever which has of late years been common in the most crowded and unhealthy parts of London, I am sure that the risk, if there be any, of beginning this sustaining treatment a little too early is much less than the risk of commencing it a little too late. If plenty of beef-tea do not suffice, you must give the patient wine, and that sometimes to a very large amount, or even brandy; the egg-flip of the Pharmacopoeia for instance, the *mistura vini gallici*. The object is to keep him alive, to keep the heart in motion, until the depressing influence of the exciting cause of the disease shall have passed by. If the wine should flush or excite him, or render the pulse hard, it must be diminished in quantity, given less frequently, or omitted altogether. If there be indications of local inflammation—pain (for example) in the caecal region, increased by pressure—leeches may be used, and wine given at the same time. There is nothing inconsistent in such mixed practice. We seek to remove the local inflammation by unloading the capillary blood-vessels in or near the part, while we uphold the general powers of the constitution which are ready to sink. The great art of getting a fever patient through a bad attack, is to have him judi-

ciously and perpetually watched, by night and by day. The remedy that is proper one hour, may do harm if pushed during the next. And there is another reason, which I may mention *en passant*, why the sick person should never be left alone, even for a moment. I have heard of more than one or two instances, of patients, in the delirium which attends the disease, getting out of bed, and out at the window, during the temporary absence of their nurse, and perishing from the fall.

When the patient relishes and wishes for the beef-tea, or the wine, that is no small warrant of the propriety and usefulness of its administration.

A word or two more may be proper, even in this cursory sketch, respecting certain incidental points of practice that are apt to arise.

Great comfort and soothing may often be obtained for the patient, when the abdomen is uneasy, by the application of a large warm linseed-meal poultice; or of the epithem called *spongio-pyline*. In the latter periods of typhoid fever it is not uncommon, even when pain is no longer excited by pressure made upon the belly, for the diarrhœa to persist, and for a troublesome degree of *meteorismus* to come on; a tympanitic distension of the intestines with gas. Under these circumstances, a large *blister*, laid over the abdomen, has often very happy effects, upon both the diarrhœa and the meteorismus. The diarrhœa, when very urgent and obstinate, may often be checked by opiate *enemata*. In some cases I have recently found catechu of great use, in these long-drawing forms of diarrhœa during, or after, fever.

Again, if the patient sink into profound coma, a blister should be applied to the shaven scalp. The sick man will sometimes awake from deep stupor while the blister is still rising.

It is always a matter of importance, as I stated before, to inquire carefully, every day, into the condition of the bladder of these fever-patients. In the state of stupor and indifference in which they often lie, they appear not to be sensible to the want of passing the urine, which collects in the bladder, and distends it enormously; not only increasing the present hazard of the patient, but laying the foundation, sometimes, of future disease of the kidneys, in case he recovers from the fever. You must not take the assurances of the nurses upon this point. They will often tell you that the patient has made plenty of water, when in fact the urine has been dribbling away from him, overflowing, while the bladder is stretched to the utmost. Feel, therefore, with your hand, and percuss the hypogastric region, as well as that of the cæcum, at every visit.

It is requisite, too, that the under surface of the patient's body should not only be kept scrupulously dry and clean, but be *looked at* every day, or twice a day. If the projecting points, the hip bones, the sacrum, the shoulders, the elbows, should become *red*, that is a sign that they are likely to slough or ulcerate. This evil consequence of continued pressure upon parts of which the vital power and healthy tone are lowered, may often be prevented by washing the erythematous spots with brandy. Should the skin be already broken, the place may be covered with soap plaster; or with the *amadou* plaster, lately introduced by Mr. Wetherfield, which does not wrinkle or ruck up. An adjustment of pillows and of posture—or the water-bed—or the water-cushion—may sometimes supersede the necessity of these local expedients.

When ulceration of the mucous follicles perforates the bowel, that catastrophe does not *always* so distinctly declare itself in fever, as in other cases. I have seen such perforation, and its resulting peritonitis, when no complaint of pain had been made by the patient, so great was his insensibility. In general, however, the rupture of the gut is denoted by symptoms which cannot be mistaken. When it does occur, there is but little chance of the patient's recovery; and that little will be best husbanded by the adoption of the plan of treatment which I formerly laid down; opiates, to check the peristaltic movements of the intestine; and a rigid adherence, for some days, to the horizontal posture. Dr. Jenner, indeed, concurs with Rokitsanski in believing that perforation of the intestine in typhoid fever, even though the passage of its contents into the cavity of the peritoneum may be for a while prevented by adhesions, is always fatal at last; that the adhesions are never permanent. It is well to bear in mind the risk of hastening, or even of causing, this fearful accident by careless or heavy pressure of the hand upon the abdomen, in a late stage of the disease.

I have seen a few instances, in which an oedematous swelling of one leg and thigh has occurred in the advanced stage of typhoid fever, like that which is incidental to parturient women, and depending upon the same cause—inflammation and obstruction of the great vein that returns the blood from the limb towards the heart. I believe that the inflammation extends itself, in such cases, from some of the smaller veins of the mesentery, which have been injured by the intestinal ulceration. Fomentation of the affected limb comprises all the remedial treatment which this accident requires or admits of.

The management of the patient during convalescence is scarcely of less importance than during the progress of the fever. The chief danger is, that his desire to be allowed to get up, and his wish to eat animal food, should be too soon indulged. The latter of these errors is more frequently the cause of a relapse than any other circumstance; and relapses are often more perilous and difficult to remedy than the original malady. You must be prepared, therefore, to withstand the solicitations of the patient and of his friends, who think that if strength be wanting, strong drinks and plenty of meat, are the things to impart it. Until the tongue is quite clean and moist, and of its natural colour, and the pulse has lost all its undue frequency, and the skin its excess of heat, the patient must be kept to broths, jellies, puddings, and preparations of the well-known farinaceous articles of food. Then he may begin with some boiled white fish, and so gradually eat his way, through chicken, and a mutton chop, to his ordinary diet again.

Such, I say, is the general plan of treatment which some observation of this disorder has persuaded me is the best. Summarily expressed, it consists in the exercise of incessant vigilance, and the adoption of the proper remedy at the proper moment. It lies between a timid or sceptical abandonment of all known resources, and a meddling-rashness in applying them. The flame of life may be suffered to expire for want of timely succour and tending, by the practitioner who folds his arms, and looks on; as it may be rudely extinguished by a restless or routine interference which has no definite or intelligible purpose. Boerhaave, in the preface to his *Aphorisms*, professes that he knows of nothing which can be fitly termed a *remedy*, “*quin solo tempestivo usu tale fiat.*” In fevers the wisdom of this maxim is eminently conspicuous. The rational objects of treatment are, to mitigate the urgency of symptoms that cannot be wholly subdued, to redress (so far as art may redress) those dangerous complications which are incidental but not essential to the disease; and to aid the conservative efforts of nature, when these manifestly languish and fail.

Dr. Robert Williams held that enemata of warm water and syrup of poppies would do all that could be done beneficially. For some time he lost only one patient out of sixty-three thus treated. This was a most encouraging result. But then, when the fever changed in species, and typhus began to prevail, as it did about the period of the arrival of the epidemic cholera, he lost one in every four or five: a very large mortality. These facts illustrate, in a strong manner, the necessity, which I have so often endeavoured to inculcate, of taking into account, when we would estimate the value of a particular remedy or plan, the difference which obtains in different epidemics, whether bad, good, or no treatment whatever be adopted. A far surer method is to compare (if you would experiment at all) two or more different modes of practice in different cases of the same epidemic. Thus Dr. Latham, finding during one season that his wards were full of fever, while yet its type was so mild that scarcely any died, thought this a favourable opportunity for trying whether mercury had any beneficial operation upon the disease. Accordingly he treated half his cases with small doses of the *hydrargyrum cum cretâ*; and the other half with the *liquor ammoniæ acetatis*, and so forth, and no mercury; and he found that the patients in the first of these classes were, on the average, convalescent sooner than those in the last. Chomel fancies, from some trials, that the chlorate of soda is a useful remedy, in addition to the general plan of management. For some time past I have myself been in the habit of giving to all my fever patients a drachm of the chlorate of potass dissolved in a pint of water, as a daily drink. Without being able to tell you precisely in what respect, in what degree, or in what way, this salt appears to do good, my own impression is strong that it does exercise some favourable influence upon the general character and course of the disorder.

It may be right that I should notice briefly a method of treating continued fevers

which has of late been strenuously advocated by Dr. Dundas. Led, apparently, by his own experience of its admirable effects in the malarious fevers of Brazil, which often run into the continued form, Dr. Dundas maintains that quinine, in large and frequently-repeated doses, is a specific cure for continued fevers as we see them here: to use his own words, that "*cinchonism* will be found to control generally the continued fever of this country in all its forms, in all its stages, and in all its complications." The condition here called "*cinchonism*" is marked by the occurrence of giddiness, deafness, and a sense of buzzing or some kind of tinnitus in the ears. Large and frequent doses of quinine exercise also a remarkable influence over the pulse, rendering its beats weaker, and slower.

This plan, thus strongly commended, has been tried with varying results by sundry medical practitioners. In some hands it has signally failed; in others it has seemed to prosper. Favourable reports are made of it from Dublin, from Drogheda, from Cork; from Liverpool, which is full of Irish poor; and from Manchester, which probably is not less so. In this town it has not succeeded, nor in Edinburgh. Dr. Barelay of St. George's Hospital, Dr. Peacock of St. Thomas's, and Professor Hughes Bennett of Edinburgh, report severally, as the upshot of numerous trials, that large and repeated doses of quinine neither cut short the fever, nor in any way favourably influenced its progress. If in any of our three species, I should have looked for success in the relapsing fever; which in some of its habits resembles the malarious fevers, and which is much more common in Ireland than elsewhere, and among Irish emigrants to our large towns. But of the cases in which this quinine treatment is reported to have effected cures, some are expressly described as instances of maculated typhus, and others as instances of typhoid fever.

[THE YELLOW FEVER. — The yellow fever is a disease which bears a close affinity, in some of the features of its etiology and symptomatology, to the febrile diseases of acknowledged malarial origin, and yet differs from these, as well as from all other fevers, in many striking and important particulars. It would appear to be, in fact, as it has been described, by several distinguished physicians, an affection *sui generis* — a specific fever.

The occurrence of yellow fever is confined, strictly, within a certain geographical range, and limited by the atmospherical temperature of the climate and season — too great, as well as too low a degree of heat appearing to be alike inimical to its production. It is invariably arrested by the appearance of frost.

The natives and permanent residents of the localities to which the disease is endemic are in a great measure exempt from its attacks, as is also the negro race.

It is a fever of but one single paroxysm, terminating, usually without the crisis of perspiration, in the great majority of cases, within seventy-two hours, and followed by an entire remission, succeeded either by complete convalescence, or, after a longer or shorter interval, by a state of exhaustion, and a series of morbid phenomena unattended with febrile reaction, eventuating, most commonly, in death.

Persons who have once suffered an attack of the fever are generally, though not invariably, exempt from a recurrence of the disease in future.

Yellow fever has received a variety of denominations, founded on the place from whence the disease is supposed to have been originally derived, on one or other of its characteristic symptoms or peculiarities, or on its supposed pathological character. The term yellow fever, by which it is known to the large majority of English and American physicians, as it involves no hypothetical views in relation to its etiology or pathology, is perhaps, in the present state of medical opinion, as good a one as can be adopted. It is based upon the icteroid hue of the surface by which the disease is usually attended in some one or other of its stages.

In its pathological character, and pathognomonic phenomena, yellow fever is invariably, one and the same disease in whatever locality it may appear, as well as during all its subsequent recurrences in the same locality. Nevertheless, it is liable to assume, in different places, at different periods, and often at the same place and during the same season, various important modifications in its general characteristics — proceeding, not from any specific difference in the nature of the disease, but from varying degrees of reaction — from a tendency to depression in the vital forces — from the preponderance of certain symptoms, appertaining or not to the disease, and vary-

ing according to the greater or fewer number of the vital organs involved, or from other causes; the whole depending on peculiarity of constitution, temperament, habits, or state of health in those attacked; on a difference of intensity in the morbid agent, and on various contingencies resulting from the nature of the localities at which the disease prevails, the degree of temperature, humidity, and other atmospherical phenomena.

Hence, it follows, that, in the examination of the disease, no invariable concatenation of phenomena, succeeding each other in regular order, as the disease progresses towards a favourable or fatal termination, are to be expected in every case.

"But a variety of groups of symptoms which, though linked together by certain phenomena—which, being pathognomonic of the disease, approximating to each other in several other respects, afford very strong evidence of their being all members of the same family—are yet sufficiently distinct in their general outline and their mode of progression, to justify their being made the subject of separate consideration. Certain of those groups of symptoms, or varieties of the same disease, prevail more generally in some regions than in others; they are also more frequently encountered in some seasons than in others, in the same place; while in some epidemics, several or all the varieties are intermingled among the different individuals attacked; in others, the fever assumes much the same character in the majority of those affected. Such being the case, it is evident that the description of the disease as it affects one individual, or one set of individuals, will not necessarily apply to another case or group of cases. In some, the fever presents itself with marks of inflammatory action of greater or less intensity; in others, that action is almost or totally absent. In some, the pathognomonic symptoms are combined with an element of malignancy and putridity which imparts a totally different aspect to the disease. In a different set this element is absent, and replaced by one of a nervous character. In some instances, phenomena not characteristic or pathognomonic of the disease, and depending on accidental complications, assume the predominance, and thereby impart still greater differences in the features of the case."—(*La Roche on Yellow Fever*, vol. i. p. 122).

In accordance with these varying characteristics of the diseases at different places, and in different seasons, or in different individuals, it has been divided into various forms. The division of all cases into the *inflammatory*, or those characterized by well marked reaction, and the *congestive*, in which this reaction is but faint or totally absent, would seem to be founded in nature. These general forms have been again subdivided, the first, into the mild, the violent, and the intense; the second, into the slight, the aggravated and the apoplectic. Under one or other of these divisions all the cases of yellow fever that present themselves may be, very conveniently, arranged.

The attack of yellow fever usually occurs in the after or fore part of the day—often during the night. It may commence abruptly, without premonitory symptoms of any kind. The patient may be struck down at once, as by a blow or lightning, and sink immediately into a state of coma. Occasionally, the attack is preceded for several days by anorexia, general uneasiness, costiveness, flatulence, heat in the stomach, lowness of spirits, vertigo, pain of the head, with dull and watery, or brilliant, yellow, or red eyes, &c. Very generally the attack is ushered in by a sense of chilliness, often alternating with glowing flushes of heat, or by a regular chill, amounting sometimes to a perfect rigor. On the other hand, in even severe and dangerous attacks, these symptoms may be absent.

Dr. Blair, (*Yellow Fever Epidemic of British Guiana*), considers that the most valuable premonitory symptoms of yellow fever, are supra-orbital pain and a punctated tongue; the first especially giving notice of an impending attack several days before it occurs.

The alternation of chilliness and heat is seldom of any duration. It soon gives way to confirmed fever, which, though continued, is more intense in the latter part of the day and during the night, than during the other portion of the twenty-four hours. In the more malignant forms of the disease there may occur but a slight reaction, or it may be entirely wanting; the pulse being feeble, soft, occasionally full, or scarcely to be felt—the patient sinking at once into a state of collapse, or of stupor, coma, and convulsions.

When febrile reaction becomes fully developed, the pulse is generally quick and

tense, and during the exacerbation full and strong, though, occasionally soft, and from ninety to one hundred and twenty in a minute. In very malignant cases it is gaseous. There is a violent throbbing and beating of the temporal arteries and carotids. The skin is hot, dry, harsh, and pungent, or it may be dry, unctuous, or perspiring, flabby and cold, except over the centre of the body. The face is either highly flushed, pale, or purplish. The eye decidedly red, sometimes as though blood-shot, hot, and more or less painful, the patient experiencing a sensation as though grit or sand had been introduced beneath the eyelids. Often the ball of the eye resembles a mass of vessels distended with blood; it is, at the same time brilliant, shining, and watery, in some cases presenting somewhat the expression peculiar to intoxication.

Dr. Blair (*op. citat.*) describes a *specific capillary irritation* that shows itself in the flush of the face, and which he pronounces to be as characteristic of yellow fever, as the hectic is of phthisis, or the fuliginous complexion of typhus. "This suffusion," he remarks, "generally occupies a zone over the eyes, and about an inch above and below them. The eyes are injected, like those of a person *just awake*, but generally without any lachrymation or photophobia, although the injection may be as intense as in ophthalmia."

Dr. Blair also remarks that, upon a careful examination of the chest, a subcutaneous rash may sometimes be observed, which occasionally extends to the arms and abdomen. The face, chest, arms and legs have likewise, in some cases, a slight purplish appearance after the second or third day, and sometimes the colour of a boiled lobster. This appearance varies much in degree, but may be detected by pressing the hand flat on the chest, when the fingers will for a short time be delineated in white with purple outline. The presence of this languid capillary circulation is, according to Dr. Blair, to be looked upon with favour. It would seem to indicate, he remarks, that the congestions were directing themselves towards the periphery of the body, thus relieving the internal organs from a part of their load. In these cases the skin is generally cool and moist, and sudamina occasionally appear.

Occasionally the condition of things described above continues from the onset of the attack to the close of the stage of reaction, or it may only partially exist during the first or second days. Sometimes profuse perspiration occurs and continues to the second or third day of the attack; at others, the temperature of the surface undergoes but little change; at others, again, the skin speedily becomes dry and cool, with complete torpor of its vessels, and an entire loss of irritability.

The foregoing symptoms are very generally attended with more or less intense pain, sometimes described as in the orbits, more rarely in the upper part of the forehead, shooting from temple to temple, but occasionally confined to one side, and in some cases extending to the occiput. This constitutes, in the majority of cases, one of the most distressing symptoms throughout the entire stage of reaction. It in most cases subsides spontaneously in the later stage of the disease. There is also pain, often of the most intense character, in the back, loins, and large joints—extending to the hips and down the thighs, or even lower. Cases occasionally occur, however, in which no such pains are experienced, or the pain in the back and limbs is dull and obscure, or that of the head is replaced by a sense of weight and stupefaction.

During this stage, the tongue is moist, covered with a thin, white, cottony fur, and most commonly red at the edges and apex; occasionally there is a soreness of the throat, sometimes even rendering deglutition difficult.

From the very onset of the disease nausea or other uneasiness of the stomach, with or without vomiting, is not unfrequently present. Generally there is a distension of the epigastrium, which is often, but not always, painful upon pressure. The stomach is irritable, especially after taking any kind of drink or aliment—it is frequently affected with a sense of nausea and more or less propensity to reject its contents. These gastric symptoms are not, however, in general fully developed until from twelve to twenty-four hours from the commencement of the attack, or at an early period of the second stage, when they become prominent.

On the first or second day of the attack, sooner or later, the patient experiences a burning pain, or a sense of stricture, weight, distension, or oppression—sometimes overwhelming—at the præcordia, which feels as if tightly bound with a cord. Tenderness or pain is experienced on pressure in most cases—it is often excessive. The irri-

tability of the stomach augments and proves distressing—every thing swallowed is rejected, and even when the stomach is undisturbed by drink or medicine its morbid contents are thrown off spontaneously—consisting either of substances that have been swallowed, mixed with clear, glairy mucus, or with matter of a sea-green colour and bitter taste. In mild cases, bilious vomiting sometimes occurs. The act of vomiting is often violent, and attended with retching and much distress and suffering. There is, at the same time, considerable, though not often insatiable thirst. The desire for cold drinks is nevertheless generally extreme.

In the early period of the attack, the matters vomited are, according to Dr. Blair, alkaline. When the second stage of the disease sets in, on the second, third, fourth, or as late as the fifth day of the disease, they become acid, and continue so to the close of the disease. The acid discharge may, at first, consist of a quantity of clear, pale, almost limpid, or slightly opalescent fluid. With this ejection the disease may terminate, or go on to a protracted period, without change in the matter vomited; usually, however, it is the precursor of the black vomit.

The urine is commonly deficient in quantity, and of a dark red colour; often depositing a copious sediment.

The urine is described, by Dr. Blair, as always acid in the first stage of yellow fever, and as continuing so generally until convalescence, when it becomes alkaline, or until it becomes heavily charged with bile. He confirms the accuracy of Dr. Collings' observations in regard to albuminosity of urine as a characteristic of the disease. The albumen generally appears on the second or third day: it has been found as early as the first day of illness, while, in a few cases, it did not appear till the day of death, and after black vomit had set in. In three cases the albuminosity was *intermittent* for one or two days. It was present in every fatal case of normal duration. It sometimes ceased in convalescence suddenly, always before the yellow suffusion of the skin and eye, or bile in the urine.

The turbidity of the urine in yellow fever is not necessarily connected with its albuminosity. The urine may be deeply tinted with bile, and highly albuminous, and yet clear. The turbidity is caused by the presence of mucous epithelial matter, coagulated albumen, and casts of urinary tubuli. It is probable that the free acid of the urine has a coagulating power, and thus sometimes causes turbidity. The presence of mucus will have a similar effect, but the turbidity then only occupies a lower stratum of the fluid, while the supernatant liquid is clear. Perfect epithelial scales are rarely found in the sediment, but broken epithelial matter is abundant. The albuminosity of the urine furnishes, according to Dr. Blair, one of the most obvious manifestations of yellow fever entering its second stage, and its extension to the great solid viscera.

A copious discharge of transparent urine, though ever so coagulable, and intensely tinged with bile, is always a favourable symptom. Scanty, oily-looking urine may almost invariably be received as a fatal indication.

The bowels are ordinarily costive—sometimes obstinately so. When stools are obtained the discharges are, at first, usually soft and feculent, seldom tinged with bile—occasionally they are of a drab colour. When cathartics have not been given, the stools, in the course of the disease, become lighter coloured, and assume often a starchy, cream-like or puruloid appearance. In a few cases they are watery, or even bloody, from the beginning of the attack.

The patient is affected with extreme restlessness and jactitation; he moans, sighs, and shifts his position continually in search of ease. In the very few cases in which jactitation is absent, the patient sometimes feels a disposition to rise from his bed, and walk about the room, his muscular strength remaining unimpaired to a degree unusual in febrile diseases. There is nevertheless, in numerous instances, from the onset of the disease, and during its entire course, universal debility.

In very many cases the patient complains of feeling as though he were unable to expand his chest or inflate his lungs. Spasmodic pains about the chest are not unfrequent. Respiration in some cases is laborious and hurried; in others, slow, and accompanied with deep and heavy sighing; in others, again, it is unaffected.

From the observations of Dr. Blair it is shown that the breath of yellow fever patients, especially in cases in which the urine is greatly diminished or suppressed,

has an ammoniacal odour. The more intense in proportion to the deficiency of the action of the kidneys.

The blood drawn in the early stage of the disease, and when there are symptoms of well marked reaction, and especially when any local inflammation is present, is sometimes of a bright arterial hue, sily, and even cupped, as in ordinary phlegmasiæ. In a very large number of cases, however, it presents neither cupping nor buffy coat, and the coagulum is flabby and easily torn. When the separation into crassamentum and serum takes place, in some cases the latter is of a natural colour; in others, it is of a yellow hue, or slightly tinged with red, and transparent; in other cases, again—more frequent in some epidemics than in others—the separation does not take place, the blood remaining for hours, or altogether the same as when first drawn. In a few cases, when drawn later in the disease, or throughout its course in cases unattended with reaction, the blood is of a dark colour, void of all inflammatory indications, and not unfrequently as fluid as molasses; while in other cases, again, it is smeared over with a pellicle of sily lymph, at the same time that the part lying at the bottom of the vessel is dissolved. In the early stage of the inflammatory form of yellow fever, the blood is very hot, and has a peculiar odour, which, according to some accurate observers, is supposed to furnish a sure indication of the true nature of the disease.

At first, the patient attacked with yellow fever is apprehensive and anxious to a distressing degree, as strongly expressed by his countenance. In very malignant cases there is an expression of apathy, or one indicating a sense of horror or intense agony. In most cases, there is some confusion of intellect attended with constant pervigilium, though without so much derangement of the reasoning faculties as to amount to decided delirium. In some cases, however, the latter symptom assumes a more marked character, the disturbance of the mind reaching to the degree constituting mania, attended with wild or fiery looks, and uncontrollable agitation of body. In other instances, there is a greater or less degree of stupor, through which, as Dr. Wood remarks, when short of coma, the signs of distress show themselves as through a veil. In not a few cases, but particularly in young persons of both sexes, and in females at two different periods of life, hemorrhages take place from one or both nostrils, during the afternoon exacerbation.

The stage of febrile reaction continues with little or no mitigation during a period varying from a few hours to two, three, or more days—the duration being commonly in inverse ratio to the violence of the attack. Having run this course, the fever, with all the attending symptoms, subsides, never more, or at least very seldom, to return—the disease being one of a single paroxysm—a period of remission or metapostosis, ensuing, during which the several organs of the system resume their normal functions. The patient feels himself able to sit up, or even get out of bed. His eyes and face become tinged with yellow, or copious evacuations of bilious matter occur by stool, or a gentle or profuse perspiration sets in, or often, without any such critical signs, convalescence is established, and the patient speedily recovers.

This, however, is the course only of the most favourable cases. In the larger number, the period of remission which follows the first stage is only temporary, and is soon succeeded by other phenomena of a more formidable character. During the very period of deceitful calm, symptoms may be detected, denoting the existence of undiminished danger. The tenderness of the epigastrium is unrelieved or even increased; the eyes and face usually acquire a yellow or orange colour, which gradually extends from the forehead to the face, neck, chest, and, finally, diffuses itself more or less generally over the whole surface. The urine also, diminished in quantity, is found tinged with the same yellow hue, or so intensely coloured as to assume a dark mahogany, or almost black appearance. The pulse is sometimes slower than in health, and in bad cases the patient betrays a little heaviness of intellect or stupor.

After a period, varying from a few hours to twenty-four or more, the symptoms just enumerated become aggravated, and others are added. In the majority of cases, the pulse remains natural, or slower than in health, and becomes still slower as the disease advances, until at length the pulsations are reduced to forty or even thirty in a minute, being, at the same time, feeble and irregular. The heart, nevertheless, even in the most malignant cases, often beats with considerable energy, even after the pulse has ceased to be felt at the wrist, &c. The tongue becomes loaded—particularly in the centre—moist or dry, and with or without redness of the edges. Thirst

increases, and is often insatiable, — nausea and vomiting, with heat in the stomach, return, and become constant, — the matter ejected being mixed with streaks or flakes of a red or brownish colour. Respiration quickens, or becomes embarrassed — the skin becomes cool, dry, and parched — the anxiety at the præcordia is now distressing, and attended with a sobbing kind of sighing, constant hiccough, and, occasionally, an expression of deep anguish and despair.

The mind often remains clear and undisturbed. There is generally an extraordinary degree of apathy evinced — the countenance presenting an expression of resignation or indifference as to the issue. Sometimes the patient evinces a kind of cheerful delirium, imagining himself well; in other cases, without delirium, he remains for a long time as if in a deep reverie, and when aroused, starts with surprise, and answers in a hurried manner. Many, while apparently in great distress, declare that they are well.

As the disease progresses, coma supervenes, from which the patient is aroused by vomiting or by dreams, and fancies himself perfectly restored to health — attempts to rise, but soon relapses into a state of insensibility. In many cases, debility is more or less considerable. In not a few, however, the patient retains, to a late period, his muscular strength — to such an extent, indeed, that he will get out of bed and walk about his room, or even beyond that, if permitted. The physiognomy is peculiar and striking, conveying, as has been well remarked, an impression at once of the malignant and dangerous nature of the disease.

Usually the foulness of the tongue increases, though it is not uncommon for it to become, after a short time, cleaner and moister than before. It is sometimes tremulous and protruded with difficulty: when the patient succeeds in showing it, he not unfrequently forgets to put it in again. It is brown and dry in the centre, or smooth, red and chapped, or white at the edges, with a black streak in the middle. The gums, lips, teeth and nostrils are covered with sordes.

As the case advances, the vomiting becomes less frequent, while irritability of the stomach, which rejects everything introduced into it, continues undiminished. When vomiting does occur, however, there is an increase in the quantity of the matter ejected, and to the momentary relief of the patient. The matters ejected from the stomach are often thrown out forcibly and to a considerable distance.

From the condition just described, recovery not unfrequently takes place — generally by a gradual receding of the symptoms, but sometimes by an evident critical revolution — the pulse acquiring force and activity, the skin becoming warm and moist, the urinary discharge becoming free and copious, the irritability of the stomach lessening and finally disappearing.

In other cases the symptoms are of a still more formidable character. The matter thrown up by vomiting consists of brown, blackish, or chocolate flakes or particles, diffused in a colourless liquid, which, though at first slightly tinged by them, ultimately becomes black and opaque, resembling coffee-grounds floating in a serous fluid. In some cases, grumous dissolved blood is thrown up. The matter vomited is acrid, often excoriating the throat, tongue and lips.

Normal black vomit is described by Dr. Blair (*op. citat.*) as having a laminar or granular sediment, of a deeper or paler shade of brown, sometimes verging on jet black, with a clearly defined supernatant serum of low specific gravity, and without mucosity, partaking of the colour of the sediment, but sometimes nearly limpid when the sediment is black, as if all the colouring matter had subsided. Many deviations from this standard occur from the presence of ingesta, hæmorrhage, and excessive secretion of mucus.

The sediment of black vomit would appear to consist of coagulated albumen and the debris of blood cells. In no case in which the black vomit was normal to the eye, was a single perfect corpuscle observed.

The colour of the black vomit, when this is pressed through a paper filter, is rendered considerably paler. It is decidedly acid — the sediment more so than the supernatant liquid. The sediment acts as a ferment on fluids containing sugar.

The presence of ammonia in black vomit, according to Dr. Blair, is universal: that is, it has always been found when looked for, and may be considered one of the tests of black vomit.

Although fatal cases of yellow fever may occur unattended with vomiting of black

matter, it is a common attendant upon the disease at the period indicated, and always portends the most imminent danger, for, though some recover after its occurrence, the number is very limited.

During the epidemic of yellow fever in British Guiana, preceding that of 1852, it was noticed, Dr. Blair informs us, that when the black vomit *preceded* the yellow suffusion of the skin, the prospects of life were improved. "The relations of this fact were not then understood. Black vomit is significant of imminent danger, from the circumstance that it is the *dernier ressort* of nature to relieve that contamination of the circulation which has been produced chiefly by impairment of the function of the kidneys, and the retention thereby within the system, of the worn-out nitrogenous elements of the body and their poisonous metamorphoses. Now, if black vomit appear early in the disease, before its march has extended to the great internal viscera, before the bile function has been disturbed, or the urine rendered albuminous, it ceases to be the significant symptom which has obtained so much ill-omened celebrity. It is then the sign of a local, instead of a constitutional affection."

The abdomen is soft, seldom meteorized. The stools, when they occur, present the same character as the matter ejected from the stomach, or resemble tar or molasses, or they may consist of blood, more or less pure. The urine becomes natural in appearance, or of a dark colour, and limpid. It is often suppressed, from deficiency of secretion, or simply retained. Sleep is interrupted, and attended generally with painful dreams. The face and breast become spotted as with ink. The jaundice—which although so common an attendant of the disease as to have given it its name, is nevertheless often, especially in rapid cases, totally absent—becomes more diffused and of a deeper hue. The skin assumes often a deep, dusky yellow, or brown, mahogany, bronze, or purple hue, imparting the idea of blood settled in a bruised part. The blood in the capillaries becomes stagnant, forming petechiæ, vibices, or large blotches, and accumulates in depending parts, and the extremities. In many cases it oozes from the nostrils, tongue, gums, anus, eyes—from leech bites, blistered surfaces, and the punctures of the veins made in venesection, and is, like all the blood in the vessels, dark coloured and dissolved.

As the disease advances, these symptoms increase in intensity; hiccough sets in, and is soon constant and accompanied with the hippocratic countenance, with difficulty of swallowing, and slow and stertorous convulsive respiration. The pulse becomes small, feeble, intermittent, and finally fades away. The alvine evacuations are highly offensive, of a cadaverous smell, and, like the urine—which, if at all secreted, assumes a blackish and bloody appearance—are voided involuntarily. Subultus tendinum not unfrequently follows; so also gangrenous spots, and, in a few cases, buboes, carbuncles, and eschars in various parts of the body. Loss of speech, dimness of vision, insensibility, low muttering delirium, and coma, at times supervene; but it is not unusual to find patients retaining their intellectual faculties unimpaired to the last. Rattling in the throat, cold clammy sweats, cadaverous and peculiarly offensive odour of the body, cold respiration, are the immediate precursors of death, which often occurs quietly, but, in other instances, in the midst of violent convulsions.

The duration of the disease varies, according to the nature of the case, from three to nine days; sometimes it is shorter, at others longer; while, in cases of recovery, the convalescence is usually secure and rapid.

Dr. Blair (*op. citat.*) states that, during the epidemic, as it occurred in British Guiana, in the years 1852 and '53, relapses were of frequent occurrence, occasioned, most likely, in a great measure, by a return of the patient to the focus of infection. These relapses were met with, almost exclusively, among the aborted cases. They frequently recurred, and were aborted several times. The primary attack was generally, but not always without albuminosity of urine, and frequently the relapse also—generally, however, in the relapse, albuminous urine was expected—even if the disease was again aborted during convalescence. Only two relapses occurred after the disease had run on to black vomit, both of which were readily aborted, although in one the relapse proceeded to albuminous urine. The tendency to relapse or second attack was generally within the first month after the primary attack.

In the foregoing account of the symptoms of yellow fever, considered in the aggregate, without reference to the particular groups in which they may present themselves,

in different cases, from the slight ephemeral to the most intense inflammatory grade, and in the several grades of the congestive form, we have followed very closely the admirable delineation of the disease given by Dr. La Roche in his late invaluable treatise on the yellow fever, using frequently his very words.

Following the author just referred to—and we know of no better guide—we shall now rapidly sketch the features of the disease as exhibited in the several grades of its inflammatory and congestive forms.

In the more intense grade of the inflammatory form, we have the initiatory chill—of a more or less decided character, followed by intense febrile action—a quick, frequent, strong and full pulse; hot, and usually dry, parched skin; violent throbbing of the temporal and carotid arteries; flushed face; red, blood-shot, brilliant, shining, watery eyes, with a sense of pain or soreness in the balls; sometimes tumid eyelids; intense pain in the supraorbital organ, in the back, thighs, and legs; tongue usually crimson red at its edges and apex, and covered with white or yellow fur; a sense of anxiety, constriction and intense pain at the præcordia; nausea, succeeded by retching and vomiting, at first of the matters swallowed, mixed with a clear, glairy mucus—occasionally with a sea-green coloured substance of a bitter taste—now and then of pure bile—often, distension of stomach, which is sometimes painful on pressure, and generally irritable to an extreme degree, especially after the first twelve or twenty-four hours of the attack. The urine is deficient in quantity, high coloured, and often albuminous and sedimentitious. There is obstinate costiveness—the stools, when obtained, being at first soft and feculent, sometimes tinged with bile; when no cathartics are used, they become, subsequently, lighter coloured and of a starchy, cream-like appearance. There are considerable jactitation and restlessness, with moaning and sighing—and a disposition to rise from bed and walk about. The respiration is laborious and hurried. There is an anxious, gloomy, sad, or impatient expression of countenance. The patient experiences great apprehension—there is confusion of intellect, constant sleeplessness. Delirium, properly speaking, is generally absent; occasionally, however, it is present, even from an early period of the attack, reaching sometimes to a degree amounting to actual mania.

The stage of reaction lasts from a few hours, to two, three, or more days—generally from sixty to seventy-two hours. It is succeeded by a remission of all the symptoms. The patient becomes at once cheerful, sits up or gets out of bed, and expresses a desire for food. The adnata of the eyes now usually assume a yellowish tinge.

The remission, which is too generally a deceitful calm, may continue from a few hours to twenty-four or thirty, and then gradually glide into the second stage. Prostration follows; the pulse becomes rapid, irregular, and depressed, or more generally, it is natural in frequency or even slower than in health. The tongue becomes loaded with a brown fur, having a darker streak along its middle, swollen, and moist, or, frequently, it is clean, with a slight pasty coating, or it may be of a deep fiery red, and, occasionally, in an advanced period, it is bloody, or dry, black, and chapped; with dark coloured sordes on the mouth, lips, gums, and nostrils. The respiration is quick and laborious; there is augmented and insatiable thirst; a distressing sense of anxiety at the præcordia, accompanied, often, with hiccough and sighing. There is an augmentation, in many cases, to an intolerable degree, of the pain at the epigastrium, which is aggravated during the vomiting that now occurs almost spontaneously—the contents of the stomach being forcibly ejected and to some distance—the matters discharged consist of brown, blackish, or chocolate flakes or particles, diffused in a colourless fluid, and gradually acquire, in fatal cases, the characteristics of black vomit. Occasionally, involuntary discharges occur from the bowels, of a black, acrid, offensive matter, sometimes resembling tar or molasses; at others the stools consist of blood. A yellow tinge, which appeared at first about the forehead and eyes, extends, subsequently, to the face, chest, and, finally, over the entire surface, gradually acquiring a deeper hue, the skin assuming a dusky, brown, mahogany, or bronze colour. The jaundiced hue of the skin is sometimes, however, absent, or restricted to the adnata of the eyes, or appears only after death. The mind is often clear and undisturbed to the last—frequently the patient exhibits a degree of apathy, with an expression of resignation and indifference. In other cases various modifications of delirium are present. Frequently, there is more or less debility; in perhaps the majority of cases, however, the patient regains his muscular strength, if

he had previously lost it, and retains it to the last. The body, in the progress of the disease, becomes cold and clammy; the urine blackish or bloody, and is often passed involuntarily; more generally it is suppressed or retained. Hæmorrhages of dark, dissolved blood, occur from all the natural outlets, and death, preceded by intolerance of light, petechiæ, meteorism, singultus, eructation of offensive gas, subsultus tendinum, convulsions or coma, closes the scene.

The rapidity of the fatal termination in this grade, is, in general proportioned to the violence of the inflammatory action of the second state, by which, in its higher degree, the vital organs may become rapidly overwhelmed and disorganized, to a degree incompatible with the continuance of their functions. Recoveries seldom occur in this form and grade of the disease; when they do, it is by a gradual amendment of the symptoms, or some critical movement taking place before the accession of black vomit.

In the milder grade of the inflammatory form, the symptoms of the first stage are pretty much the same as in the more intense grade, but less violent, rapid, and tumultuous. It is attended by more decided exacerbations and abatement of the fever—the abatement often approaches to an actual remission. It often extends to four or five days. The second period or that of remission is more perfect, and in many cases the harbinger of recovery—convalescence dating from the final subsidence of the fever—the disease terminating with bilious critical discharges by the bowels, a moisture over the skin, or diaphoresis, a copious emission of urine, or a hæmorrhage from the nose—with or without jaundice—often without any evident crisis.

In other cases, however, the remission is followed by many of the symptoms which mark the second stage of the preceding grade. These sometimes assume a character of great malignancy, and if not arrested by art, or the recuperative efforts of nature, terminate in death. In other cases, they stop short of black vomit, and the patient is gradually restored to health. In others again, though in a very small number, recovery ensues, even after the supervention of the black vomit, and other usually fatal symptoms. The disease in this grade is evidently of a less malignant character, and within the range of remedial agencies. The bowels are acted upon without much difficulty by cathartics or enemata, the operation of which is productive of relief, the pain and affection of the head and other parts are under the control of proper depleting remedies, general and local, revulsives, &c.; the gastric irritability, though obstinate, is not always as uncontrollable as in the more intense grade, and diaphoresis is generally easily obtained by external and internal means.

In the ephemeral grade of the inflammatory form, although there are the same general features, the same outline of phenomena, as characterize the preceding grades, they are of a still milder and more manageable nature—and terminate, under proper and even mild treatment, sometimes in a single day. Occasionally, however, the fever continues from three to five days, when, in some cases, it is attended with slight and imperfect remissions.

The symptoms indicative of an open and well developed febrile paroxysm subside, sometimes, suddenly; at others, the crisis being marked by increased alvine evacuations, by diaphoresis, or epistaxis.

In the aggravated grade of the congestive form, the attack occurs suddenly. From the outset there is considerable prostration. In most cases, from an early period, there is giddiness, stupor, almost unconquerable disposition to sleep, loss of memory, and a desire to be left alone. There is a sense of weight and oppression, rather than of acute pain in the head. In a few cases, there is delirium, either transient, or ending in confirmed coma. The face is pale, purplish, or livid in colour, with a stolid or apathetic expression of countenance—the patient being taciturn, and uttering no complaint. Sometimes there is entire insensibility, the eyes being wide open, at others there is an expression indicative of distress, horror, or even intense agony.

There are obscure pains of the loins and extremities, and a feeling of helpless debility about the spine—most distressing at the sacrum—sometimes attended with a paralytic failure of the lower extremities. There is a dull, red, glassy, or drunken, idiotic look of the eyes, with, in some cases, a dilatation of the pupils, and sleepy movement. The skin is always deficient in tone, dry, dense, or unctuous, or sometimes covered with, and as if melting in, sweat. It is generally cool—sometimes cold, except at the central portions of the body, which are hot; in some instances it is

smooth and white, and occasionally loses, more or less completely, its sensibility and irritability. The pulse is sometimes accelerated, at others not more frequent than in health; sometimes full, at others small. It is always weak, offering no resistance to the pressure of the finger; occasionally it is scarcely perceptible at the wrist, though at the same time the heart and carotids may be throbbing forcibly. As the disease advances, it diminishes in frequency, the beats not amounting, at times, to more than forty, or even thirty in a minute. In some cases it becomes intermittent. When blood is drawn, it is generally found black or discoloured; it seldom retains its natural character.

There is tenderness of the epigastrium, tension of the hypochondria, weight and oppression at the præcordia. There is early irritability of the stomach—and vomiting—the matter ejected rapidly assuming the character of black vomit. The discharges from the bowels are scanty—cream or clay-coloured, puruloid, or gelatinous—sometimes of a pea-green colour, or black and bloody. The respiration is laborious. The tongue, sometimes natural, is at others, first pasty, with patches of white fur; its edges and apex being red. Occasionally, it appears as though seared with a hot iron. It is often tremulous, and when the patient puts it out he often forgets to draw it in again. It sometimes becomes dry, while the papillæ are separated by deep fissures. There are, also, orthopnoea, sore throat, deep and interrupted sighs, hæmorrhages of dissolved blood from one or more of the natural outlets, a yellow or bronze colour of the skin, suppression of urine, extreme restlessness, low, monotonous wailing, and other symptoms indicative of the utmost danger, or the approach of death.

In some cases, the leading symptom is an overwhelming oppression at the præcordia, attended with slow, laboured respiration, deep sighs, and groans. In others, constant vomiting, and intense epigastric distress, quickly followed by black vomit and death; in other cases, again, the pulse is nearly natural, the tongue clean, and the stomach calm, but excessive restlessness, anxiety and distress ensue, soon followed by black vomit and fatal collapse.

In some instances, the disease, though marked by the same train of phenomena, assumes, nevertheless, in its course, a less formidable character, stops short of the black vomit and other fatal symptoms, and proves comparatively mild and manageable. As a general rule, however, but very few of those attacked with this form of the disease recover.

The adynamic or typhoid grade occurs in persons deficient in vital power, or under circumstances tending to foster or develop the typhoid diathesis. It is generally ushered in by a sense of chilliness, succeeded by one of burning heat, partially distributed over the body—affecting principally the under parts of the arms, and inner surface of the thighs. The circulation is depressed, the pulse being small and weak. The eyes have a dingy appearance. There is severe pain of the head, with confusion of thought and dimness of vision. The skin assumes an olive hue, and is covered with petechiæ or vibices. Hæmorrhage from the natural outlets, leech bites, &c., follow, as also from excoriations about the nose, mouth, or other parts; gangrene of blistered surfaces, sometimes anthrax, buboes, and, more frequently, venous infiltration under the skin, or in the interstices of the muscles.

The walking grade of yellow fever is so named from the fact that in it the organs of animal life remain almost unaffected. The patient most frequently sauntering about his room, or, at times, even walking in the streets for recreation or on business. In some instances he confesses to a feeling of weakness, but, in others, he exhibits at intervals, or throughout, indications of considerable muscular strength. He complains of nothing, denies his being ill, amuses himself in reading or otherwise, and to a casual observer, appears to be slightly, if at all, indisposed. The physician will be able, however, generally to observe that the patient exhibits an unusual expression of countenance—dulness and listlessness. The eye is watery—the complexion almost of a mahogany hue—the pulse exceedingly weak, or even totally absent. Black vomit overtakes him, even while occupied as described, or very soon after, and death speedily ensues.

In some of the cases of the apoplectic grade, the patient is struck down suddenly as if by lightning, with stupor or coma, and death, preceded by convulsions, soon follows; or, without the slightest premonition, he is instantly seized with vertigo and confusion of mind; accompanied with dull pain and fulness in the head—spasmodic

pain and considerable debility in the legs—coldness, debility, and a sense of uneasiness in the spinal region—a pulse varying, in different cases, in fulness and frequency, but always weak and finally faltering,—a cold skin, sometimes dry and flabby, but generally unctuous or bedewed with cold perspiration—and irritability of stomach. The patient lies as if stunned; with dilated pupils and an expression of gloom on his countenance. An effort at reaction occasionally takes place—but scarcely ever leads to a favourable result. More generally, the patient becomes perfectly comatose, the eyes assume a glassy appearance, the pulse fades away, involuntary discharges and profuse hæmorrhage supervene, and death soon ensues.

“The yellow fever is far, however, from pursuing, always, everywhere, and under all circumstances, the even tenor of its course, without experiencing more or less important modifications from other causes which may operate on the system in conjunction with, or antecedently to, that by which it is produced; while the special morbid agent which gives rise to it, seldom fails to modify, to some extent—when it prevails extensively and with great virulence—other diseases arising from the impress of other causes. Hence arise, on the one hand, numerous complications of the fever with complaints of various kinds; in other words, cases in which, to the symptoms of the fever, are added others indicating the coexistence of some other disease, which owes its origin to the operation of distinct causes; and, on the other hand, those modifications of prevailing complaints occasioned by an impress of the yellow fever cause, which, though not sufficiently powerful to produce the fever to its full extent, is enough so to stamp those complaints with some of its features, and, in the language of Dr. Rush, to make them wear its livery.”—*La Roche, op. citat.*

Dr. Blair describes four distinct causes of death in yellow fever; they may, however, be blended occasionally in the same case. They are syncope, uræmia, apoplexy, and asphyxia. Death from syncope may be owing to excessive discharges of black vomit, or from hæmorrhage, as profuse epistaxis, or bleeding from the mouth and gums, or from the black vomit and hæmorrhage combined. If before death there is entire suppression of urine, and the black vomit is not copious or has ceased, the circulation becomes contaminated, and in its mildest form the action of the impure blood upon the brain, produces an effect not unlike alcoholic inebriation. Patients, a few hours preceding death, have been known to sit up in bed, and joke with their comrades, or in a chair regaling themselves with a pipe of tobacco. When all the secretions and excretions are locked up, as occasionally happens, the symptoms of uræmia poisoning are of a more violent character; the sensorium is painfully affected—irritability of temper, screams and wild ravings ensue, followed by convulsions, coma, and death.

Death by apoplexy may occur as the result of congestion and extravasation of blood on the brain. Death from asphyxia may occur from excessive pulmonary engorgement, or from laryngeal suffocation.

In proceeding to consider the pathological anatomy of yellow fever, we may remark in the outset, that cases occasionally present themselves, especially when the disease has proved suddenly fatal or has run a very rapid course, in which no appreciable lesion in any of the organs or tissues can be discovered on dissection, or lesions of too slight a character to permit us to refer to them any agency in the production of the phenomena of the disease, or its fatal termination. In the great majority of cases, however, morbid changes, often considerable, are to be detected, by which the disease can usually be identified, while they throw more or less light on its pathology.

The surface of the body in general presents a yellow colour, varying from a pale to a dark orange or brown. In many cases it has a greenish, or mahogany, or leaden hue, or even a purple or black aspect. The lighter shades of colouration, are usually observed in subjects carried off rapidly and by an inflammatory attack, the others in such as have fallen victims to attacks of a malignant or protracted character. Sometimes a pale yellow line, mingling with the other colours, can be traced from the nose to the pubes. The discolouration may be confined to the face or eyes, neck or chest, or extend over the entire surface. It is generally deeper on the face and trunk than on the extremities. It is more intense and general after than before death; it may even not have appeared previously.

The scrotum, penis, fingers, toes, and ears, which, especially a short period before dissolution, are often very much discoloured from stagnation of blood, become, as do

also the back and neck, of a dark purplish hue. These are cadaveric effects. Ecchymoses, in spots of different sizes or shape, round or in stripes, sometimes occupy the forehead, upper portion of the face, as also the trunk and extremities. These latter are the results of disease, and appear before death. The surface is, sometimes, also covered with minute ecchymoidal spots, bearing some analogy to petechiæ, and increasing in number after death.

In many cases the cellular membrane and fat are found to partake of the yellow colour of the skin. This occurs less frequently in malignant and congestive, than in ordinary cases of the disease. Extravasations of blood in the subcutaneous cellular membrane, and between the interstices of the muscles, are not uncommon. In some cases, livid and gangrenous spots occur on portions of the body.

The joints and muscles are generally rigid and stiff; and the latter, in those who have died of the malignant form of the disease, are often of a dusky or dark hue. They are generally softened in texture and easily torn or broken down by pressure. Sometimes, especially after ordinary and inflammatory cases, they are but little, if at all changed in colour and firmness. They are occasionally pale, as if they had been submitted to prolonged maceration.

The face, in some cases, is tumefied, in others shrunken.

The brain is often found entirely free from diseased changes. Traces of inflammation are occasionally, however, detected in it or its membranes, but have no direct relationship to the yellow fever. In many cases, the pericranium, the sinuses, and the vessels of the brain are more or less gorged or congested with blood. In some the membranes alone, or together with the brain, are injected throughout or in patches; and in many, a fluid of a limpid or yellow colour, or mixed with blood, is effused in the ventricles, at the basis, or on the surface of the brain, or in its membranes.

Nearly the same remarks may be made in reference to the lesions detected in the spinal marrow. When unequivocal traces of inflammation of this part or its membranes are present, these must be referred to some accidental complication, and not as forming an essential part of the disease. Many of the changes met with in the spinal marrow after yellow fever, are probably to be referred to mere congestion, and the hæmorrhagic tendency which constitutes a main characteristic of the disease.

Various morbid appearances of the ganglia and ganglionic nerves have been described as occasionally met with after yellow fever. No one of these are invariably present — all of them are frequently absent — they often exist in subjects who have died of diseases having not the least resemblance to yellow fever; hence when present they are not to be viewed as among the true anatomical characters of the latter.

In general, the respiratory organs present no appearances indicating that they partake largely and necessarily in the diseased action of the system in yellow fever. The lungs are often found, at their posterior or lower portions, more or less gorged with dark coloured and altered blood. They are frequently in parts or throughout, black, resembling a sponge; in substance sometimes firm and dense, not unlike the substance of the spleen, or gorged with blood, black and dissolved, and do not collapse upon the removal of the sternum. Not unfrequently their surface is covered with melanæ patches or ecchymoses of from two to five lines diameter, or masses of a black colour, impermeable to the air.

The bronchial mucous membrane is in general free from disease; sometimes it is injected, or spotted with blood, or even inflamed. The pleura is usually unaltered, the ecchymoid spots noticed upon it being situated in the cellular membrane beneath, or in the substance of the lungs. In some cases the pleura has been found inflamed, or containing more or less effused serum of a yellowish, orange, or reddish colour, with or without marks of inflammation. In a few, the fluid is of a sanguinolent character, and resembles, more or less closely, the black vomit.

The substance of the heart, like that of other muscles, is sometimes of a dusky colour, and soft and more flabby than natural, and easily broken down by pressure between the fingers. In perhaps the greater number of instances, however, the organ retains its natural appearance. The pericardium, which generally appears healthy, sometimes contains a notable, though not unusual quantity of serous fluid of a yellow or reddish colour. The endocardium, in some cases, is slightly red, apparently the effect of staining. In many others it is, as all the fibrous parts, the valves, &c., of a

yellowish colour, which often extends into the aorta and the larger vessels. On the surface of the former, spots closely resembling petechiæ, are sometimes observed. The cavities of the heart contain a greater or less quantity of blood, usually dark coloured, and for the most part grumous or fluid, with or without coagula of the same colour. In a large number of cases these cavities—especially the ventricles—contain albuminous concretions, varying in size and consistency, and of a transparent yellow colour, having the appearance of meat-jelly or fine amber. They penetrate sometimes into the aorta.

The stomach is the organ most generally and seriously implicated in yellow fever—in it indications of disease are most frequently discovered after death. Externally it is sometimes of a yellow colour, but generally retains its normal appearance. It is usually found to contain more or less of matter similar in appearance to the black matter thrown up by vomiting in the latter stages of the disease. This matter has been shown by recent investigations to be blood—most probably diseased in character—poured out by the capillary vessels of the digestive mucous membrane, and still further changed by the action of the acid it meets with in the cavity of the stomach. In some cases, the contents of the stomach consist of blood more or less pure, with or without the coagula, and generally combined with a portion of glairy matter, and substances swallowed a short time before death. In some instances, the mucous coat is smeared over with a dark, adhesive jelly-like substance, containing portions of blood. Under this substance, and sometimes when it does not exist, we find a layer of greyish matter, not unlike a mixture of linseed meal. In a certain number of cases, the mucous coat, when cleansed from these various coatings, is found to present a normal appearance. In many instances it is even whiter than in its normal state, from the effusion from its vessels, in all probability, of the blood with which they had been loaded, in the form of black vomit.

In the greater number of instances, however, the mucous membrane of the stomach is found more or less diseased, indicating that it had been the seat of inflammation more or less extended and of different grades of intensity. Thus the stomach is sometimes contracted, at others distended. The longitudinal rugæ are enlarged. The surface has often a vermicular appearance, being corrugated and thrown into numerous folds. Its capillary vessels are injected to a greater or less extent with blood. It is reddened, presenting various shades, from a rose to an intense dark hue, or it may be leaden, livid, or even nearly black. The discolouration being either uniform in appearance or in the form of arborizations—it may extend over the greater portion of the mucous coat, or be confined to the cardiac or pyloric orifices, the large curvature, presenting itself in patches different in number and size in different cases. Streaks or spots of a purple colour, spread in various directions over both the altered and healthy parts. The spots, differing in size, have the appearance of ecchymoses. At other times, with or without these, there are numerous small, dark red, or violet round spots, resembling petechiæ, contrasting very decidedly with the rose hue of the mucous membrane upon which they are scattered. The lining membrane may, besides, present abrasions, or small depressions or pits, like holes or furrows, as though a portion of the tissue had been removed. It is frequently mammillated even to a remarkable degree, also, more or less considerably thickened and opaque. It is sometimes softened, and easily detached, especially about the great *cul-de-sac*. In a few cases it is ulcerated, or presents a gangrenous change. Sometimes, more especially after malignant or congestive attacks, an effusion is discovered under the mucous tissue.

“These changes are not all found in the same cases, nor are they present at whatever period of the disease the patient may have succumbed, or whatever may have been the character and duration of the disease. In congestive or malignant cases, we find more or less injection of the capillaries—the redness generally of a dark hue. There are usually ecchymoses, and petechiæ, but no thickening, softening, or similar changes. These, together with capillary injection, are, as a general rule, met with after attacks of a different character. In these, if death takes place on the second, third, or fourth day, the increased vascularity is noticed in bright red, or dark, dusky patches, more generally confined to the vicinity of the orifices, but sometimes extending to the greater part of the membrane. If the case has been protracted to a later period—to the sixth, seventh, eighth, or ninth day—a larger portion of the surface is

found involved, and we may expect to find it of a leaden, livid, greenish, or mottled appearance, and presenting the marks of disorganization already noticed. In instances unattended with these changes, in which there is mere redness, with ecchymoid and petechial spots, these are probably not the effect of cadaveric changes, for they are found immediately after death, and too soon to be attributed to such cause, they must rather be referred to simple congestion. But whenever this redness is attended with thickening, or softening, or the mammilated appearance of the membrane, we cannot but join in opinion with Louis in attributing these changes to an inflammatory condition of the parts," (*La Roche*). The appearances discovered in the œsophagus and intestines do not differ materially from those exhibited by the stomach. The intestines, when the case has been rapid, contain often bilious, yellow or ordinary excrementitious matter—at other times their contents are brown, black, thick or jelly-like, often of a tar-like appearance—or they may be fluid, of a reddish or soot colour, or even consist of blood, more or less pure. Sometimes they are whitish, and often present the characteristics of the black vomit. The intestines, in a few instances, are contracted to a greater or less degree, and with more or less force. Extensive invaginations are occasionally observed. The duodenum and upper portions of the jejunum are the parts most generally affected, though, in other cases, the lower portions of the ileum are more implicated than the latter.

The glands of the intestines, especially those of Brunner, are occasionally found in a diseased or abnormal condition.

The gall-bladder is either empty, diminished in size—withered, as it were, or distended, with its usual amount of bile more or less natural in quality—or its contents may be small in quantity, viscid, inspissated, or mixed with more mucus than common. It is either dark green, blackish-brown, or of an obscure red colour, and of the consistence of tar. Not unfrequently the gall-bladder contains a quantity of thick viscous blood, grumous, tar-like, or ink-coloured, or of serum, and more rarely of pus. Its internal membrane is often spotted, or punctated, and sometimes largely injected with blood of a bright or obscure red or brown, or even dark colour. It is said often to present traces of unequivocal inflammation.

The liver is usually of a light yellow, nankeen, fresh butter, straw, coffee and milk, gum yellow, buff, gamboge, light orange, or pistachio colour. In some cases, this discolouration occupies the whole surface, and pervades the entire parenchyma of the organ; while, again, in others, it extends only partially over both, giving a marbled appearance—presenting throughout patches or regular striæ, and alternating with others of a dark green colour. It is limited occasionally to a single lobe, usually the left. Recent observations would seem to show that this discoloration is due to a fatty degeneration of the organ.

"Frequently, however, as this peculiar coloration of the liver has been observed, it is far from being universally so; cases occurring in which the organ is found of a different hue—dark yellow, brown, red, purple, bluish, slate, chocolate, or livid. It has been described as of a brick colour, and compared to rhubarb, or to Peruvian bark. In other cases, again, it retains its natural appearance externally and internally, and is otherwise healthy. The parenchyma, when divided, is often found hard, dry, tough, and sometimes dry and brittle, and more or less devoid of blood; while, in some cases, the viscus is more or less gorged with blood, and softer in texture than natural. In some cases, the biliary pores contain bile, but more frequently there is no indication of biliary secretion."—(*La Roche*).

Though often more or less enlarged, and at other times shrunken, the liver seldom exhibits traces of inflammation, and, if these are discovered, they must be viewed simply as the effect of complications; while the alteration in, or suppression of, the secretory function of that organ, may justly be referred to some cause different from that morbid state.

The kidneys are occasionally found in a normal state, or with only trifling marks of having partaken of the disease. In other cases they are congested—filled, more or less, like other organs, with dark fluid blood, the mucous membrane of the pelvis and infundibulum being sometimes minutely spotted with blood, or ecchymoses; or they exhibit a morbid condition similar to that observed in Bright's disease. In other cases they bear the marks of acute inflammation.

The bladder is often contracted; sometimes its coats are thickened. The mucous

coat is generally healthy, or only injected and dotted with small points, or ecchymosed. In some cases it is covered with a yellow mucus. The bladder is often empty, or nearly so—it may, however, contain more or less urine, natural in appearance, bloody, or more or less bloody. Occasionally it contains black matter resembling that ejected from the stomach, or pure blood.

The spleen is usually of a darker colour than natural—sometimes somewhat enlarged, and friable. It is often moderately softened, and generally engorged with dark currant-jelly-like blood. In some cases it is found unchanged. No prominent change has been detected in the pancreas.

In some cases the penis is found covered with eschars; and the scrotum swollen and thickened—brown or black, as in senile gangrene—sometimes with excoarations.

The yellow fever is a disease of hot climates and hot seasons. In every locality where the disease prevails as an endemic, or in an epidemic form, the thermometer gives us an average heat of 80°, or thereabouts. In all these places, the disease shows itself only at the period of the year when the heat is greatest—and usually with the most severity during seasons of the highest temperature, seldom attaining its greatest degree of intensity before the heat has continued at its maximum average for some time. Heat alone, however, is insufficient to produce the disease, for in climates and seasons of a higher and longer continued average temperature than that given above, it has not made its appearance.

An excess, or at least a certain degree, of atmospherical humidity would also appear to be necessary to the development of yellow fever. The disease frequently occurs during or immediately succeeding rainy seasons, and is, ordinarily, encountered in damp localities, where rain is common and falls abundantly; where the soil, previously dry, has been rendered wet by copious rain, freshets, overflows, &c., or where the dew point is high, and vesicular humidity generally or often noticed, or is considerable at the time. But facts innumerable go to show that humidity combined with heat, is not sufficient alone, for the production of fever.

Some local cause capable, when acted upon by heat, moisture, and perhaps other conditions of the atmosphere, the exact character and influence of which have not as yet been fully observed, of generating a special poison—by which an infection of the surrounding atmosphere is produced; which infected atmosphere, when taken into the system—particularly in one especially predisposed to its morbid influence—the poison it contains enters the blood and is by it distributed throughout the body—impairing the vital properties of the blood itself, and producing a morbid impression upon the nervous centres—and in this manner deranging the functions of, and producing the morbid conditions which we detect in the several organs and tissues of the body. The variation in the character and extent of these lesions in different subjects depending on the difference of age, habits of body, and numerous other circumstances connected with the individual; on the degree and concentration and violence of the efficient cause; on the peculiar character of the epidemic constitution of the atmosphere; on the nature of the localities and numerous other modifying agencies.

It would be impossible to enter here into the evidence of the invariable origin of yellow fever from a specific poison existing in the air of the localities where it prevails, and produced from causes there existing. That evidence is in our opinion conclusive, and irrefutable.

In referring the production of the yellow fever, in every instance to a local malarial cause, we mean, also, to deny its propagation by contagion;—we are acquainted with no other disease of a strictly local origin ever evincing a contagious character or assuming such a character under any possible contingency. The facts, in evidence of the non-contagious character of yellow fever, are well authenticated and numerous—and sufficiently establish the correctness of the position. As a general rule, we use the words of Dr. La Roche, the disease may be regarded as one of low, flat, and level localities, and as appertaining more especially to hot latitudes. It never shows itself beyond a certain elevation, the limits of its altitudinal zone being even more restricted than those of ordinary paludal fevers.

The inability of the yellow fever to be generated at a high elevation above the level of the sea, depends in part on the greater elasticity and purity of the air, on a diminution of atmospherical pressure, and on a more thorough ventilation. But the

main cause is the absence there of the degree of atmospheric heat, which, as we have seen, is indispensably necessary for the elaboration of the morbid agent to which the disease is due. For the same reason, in part, though not exclusively, its geographical limits are restricted within certain bounds in a northern direction, while, in a southern, the same effects are produced, as it would seem, by an excess of heat, and a variety of influences of a meteorological and telluric nature. Be the causes, however, what they may, on one point there can be no doubt—that the yellow fever has geographical limits, beyond which it does not appear—and that within those very limits there are many places where its usual apparent cause would seem to exist, but where, nevertheless, it has never shown itself, or has done so very seldom. The West Indian Islands, and part of the coast of South and North America, constitute its proper soil. From Brazil to Charleston, in one direction, and from Barbadoes to Tampico in another, the causes of the fever are in constant though unequal force, in regard to different seasons and localities. It prevails often, though not very generally, in some places more north than Charleston; visits, occasionally, the Atlantic cities of our Middle States, and has ascended as far as Boston, while in the Mississippi Valley it has prevailed as high as Memphis, perhaps Gallipolis, or even higher. In an eastern direction, but within the same latitudes, it has extended to Cadiz, Xeres, Carthagenia, Malaga, Alicant, Seville, Barcelona, and other cities of the coast and the interior of Spain. It has prevailed several times at Gibraltar, once at Rocheford, once at Lisbon, and once at Leghorn. Hence, we find it embracing a considerable portion of the earth's surface. In its fullest latitudinal extension, it reaches to between the twenty-second and twenty-third degrees south of the equator, and, on the other side, to the forty-second degree on the Atlantic coast, to the thirty-fifth degree on our western waters, and to the 8.56° on the Pacific. Considered only in reference to its legitimate longitudinal boundaries, it stretches from about the sixtieth to the ninety-seventh degree of longitude east of Greenwich. Its true area includes the Caribbean and other islands called the West Indies, and Bahamas, the contiguous coast of Colombia and Guatimala and the extensive shores of the Mexican Gulf, sweeping from Cape Catoche on the west, to Cape Sable on the east, and running thence along the coast of America to Wilmington, (N. C.,) Norfolk, Baltimore, Philadelphia, New York, Boston, and intermediate towns: in some of which places it is an occasional, not annual, or even frequent visitor.

“Until recently, the river Amazon, which divides Brazil from Guiana, formed the boundary of the disease south of the equatorial line; for, although it is said to have prevailed at Olinda from 1687 to 1694, and to have shown itself as far as Montevideo in the beginning of the present century, the latter circumstance is open to some doubt, while in Brazil, from the close of the seventeenth century to the middle of the present, the disease was not observed. Since 1850, it has invaded Rio Janeiro, Bahia, Pernambuco, and other places of that country. It is, in a great measure, a stranger to the Pacific, having prevailed but once at Panama, twice at Guayaquil, and once at Callao. It does not appear in the East Indies. It has never prevailed in China, Cochin China, Singapore, Siam, Ceylon; it has prevailed occasionally on the African coast, Senegal, and the Gold coast, and has but three times, in the space of eight-six years, showed itself in Cayenne.

“Within those limits, it has, in some one or more places, originated and prevailed to a greater or less extent—occasionally or frequently—either as an endemic, or as a mild or wide-spreading epidemic. Beyond these it never shows itself; and though—whether north or south, east or west—it does not reach the point at which common malarial fevers stop, it approximates to these diseases; so far, especially, as its northern or western extension is concerned, it being circumscribed within certain bounds; for they, too, have their limits. The effect in both instances is due to modifications in the same morbid agencies.”—*La Roche, opera citat.*

Acclimatization is preventive of an attack of yellow fever. Thus, in places where the yellow fever is endemic—where the climate is continuously warm, and the causes of the disease are more or less permanent, or frequently evolved—individuals accustomed by long and continued residence to the influence of the climate, and the agency of those causes, lose their susceptibility to an attack. But after a prolonged residence in cold and more salubrious localities, the individuals thus protected lose, to a certain extent, their acclimatization, and on their return to their former places of resi-

dence become once more liable to suffer from the disease. The children, too, of natives of, or of those acclimatized to tropical regions, do not enjoy the same advantages in regard to protection, as their parents, but acquire them rapidly as they advance in age. The residents of some portions of tropical regions suffer to a certain extent from the disease, on removing to another portion less salubrious. The protection of acclimatization is also, to some extent lost, by a long exemption of the locality from local sources of infection, or by the prevalence, during several successive summers, of a cooler and purer atmosphere than before.

The most susceptible subjects of yellow fever are those who have recently arrived in infected localities, particularly the inhabitants of northern climates—the predisposition to an attack increasing with the degree of the northern latitude from which the stranger has arrived, and the shortness of the interval that has passed since he left the northern for the equatorial region. Even the inhabitants of situations in the neighbourhood of infected localities, but more elevated and salubrious, or of rural districts generally, though less prone to the disease than strangers from cold climates, are, nevertheless, liable to suffer when they venture into an infected place.

As a general rule, an attack of the yellow fever exhausts the susceptibility of the system to further attacks, or renders it less liable to be severely affected by the poison of the disease. Second attacks of yellow fever, in individuals who have passed through the disease, are somewhat rare; the immunity thus obtained is greater than that derived from simple acclimatization. Second attacks constitute, therefore, exceptions to a rule, and are perhaps but little more frequently met with than second attacks of other diseases through which the system usually passes but once.

Individuals of the sanguine temperament—the robust, strong, and plethoric, are those most prone to the disease—especially when their mode of living is calculated to keep up that temperament, or to bring out its elements in bolder relief. In times of unusually violent epidemics, when the fever spares none, individuals of all temperaments become alike its victims. As a general rule, females are less obnoxious to the impression of the poison productive of yellow fever than individuals of the other sex, and when attacked have the disease in a milder form. The disease, usually, effects in preference individuals of adult age—sparing, to a greater or less extent, young children as well as persons advanced in life.

“In all places, whether within the tropics or in temperate climates, in which the yellow fever has manifested itself—sporadically or epidemically—the negro race has manifested a greater or less susceptibility to the influence of those causes that give rise to the disease; every where, however, that susceptibility is far inferior to that exhibited by the white race—the disease in the former spreading less extensively, and assuming usually a milder and more tractable character. In warm regions, the almost general exemption of the blacks is due, in some measure, to their being acclimatized to the country—a circumstance they share with creoles, and those who are inured to the climate; their more frequent liability to the disease in colder than in warmer regions, is due to the same cause which renders the white inhabitants, whether natives or long residents, more prone to the disease than creoles—the want of acclimatization. By losing, through means of expatriation, the power of resistance imparted by acclimatization, they are placed much on the same footing as negroes of temperate climates, being no longer as surely exempt as they were before from the disease when again they are exposed to its influence.”—*La Roche*.

Fear, in common with all the depressing passions, is a powerful predisposing cause of yellow fever.

“Excessive joy, fits of anger, by stimulating the action of the heart and arterics, as well as the nervous system generally; strong emotions of any kind; despondency from pecuniary or other losses; disappointment from even trivial causes; intense mental application, are no less to be deprecated, though producing their effects in a different way; while the feeling of hope, courage, cheerfulness, as well as equanimity of temper, have the contrary tendency, of shielding the system from the morbid influence of the efficient cause of the disease, both by promoting the healthful play of the functions, and placing the happy possessor of them beyond the reach of the depressing passions. They prove powerful adjuvants of treatment.”—*La Roche*.

Whilst sleep, especially in infected and exposed localities, must be viewed as a pre-

disposing or exciting agent of the disease, the deprivation of it—watchfulness from any cause—gives rise to the same effect.

Intemperance in respect both to food and drink; the use, especially when carried to excess, of aliments of an exciting and nutritious, as well as those of a crude and indigestible character; unripe or acid fruit, perhaps still more particularly the use of ardent spirits, and, indeed, of stimulating liquors of any kind, have almost invariably exhibited a tendency to excite the development of the yellow fever. The danger arising from such indulgences has been fully recognized from the earliest period, and is recorded by almost every writer, ancient and modern, who has treated of the cause of the disease. It is proper, however, to remark, that a sudden change from a generous to an abstemious diet, will be apt to bring on an attack of the disease in individuals who might otherwise, in all probability, have escaped. A too rigid and abstemious diet is equally injurious.

Immoderate evacuations; venereal excesses; fatigue of body from whatever cause induced, as well as all other things calculated to debilitate the system, may be ranked among the predisposing and exciting causes of yellow fever.

Butchers, curriers, tanners, soap-boilers, tallow-chandlers, scavengers, and in general, all those who habitually breathe an unwholesome atmosphere are far less liable to the disease than others differently circumstanced. While, on the other hand, cooks, bakers, black and whitesmiths, hatters, tailors, and sugar-refiners, are reputed to be particularly exposed to attacks of the disease.

Among the more frequent exciting causes of yellow fever may be ranked exposure to cold in any way, especially when the body is heated or perspiring, through the effect of exercise or otherwise, as also exposure to the coolness and chilliness of night air, to a shower of rain, &c., sleeping in the open air, or exposure in any manner to the night air—lying upon the ground, drinking large draughts of cold liquors, especially water.

The suppression of any of the natural, or of any artificial excretions, as also, the sudden diminution or removal of irritations to which the system has become in some measure accustomed, issues, blisters, alvine evacuations, ulcers, chronic cutaneous eruptions, etc., have been found to produce an injurious result, and prove the harbingers of an attack of the fever.

The diagnosis of yellow fever, under ordinary circumstances, and to one familiar with its phenomena and course, as contrasted with those of other fevers endemic to the same localities and prevalent at a similar season of the year, is attended with little difficulty. There is not, however, a single symptom appertaining to the disease, when viewed by itself, or without regard to the degree of its frequency, that can, strictly speaking, be considered as really pathognomonic, each of its more prominent symptoms, is, at times, absent in cases of undoubted character, and each will be found to occur in other diseases, but remotely connected with it. But, as Dr. La Roche very properly remarks, when viewed in connection with each other—when found associated together, or when the greater number of them are present in the same case—especially when this assemblage is found to hold in a large number of individuals affected, the result is different. Under those circumstances, the peculiar jaundice described, varying from the bright yellow to a dark mahogany or livid hue—the emission from the stomach of the dark coffee-ground matter, so well known under the name of black vomit—the injected, brilliant, transparent, fiery, and glassy eye—the thin, slimy, white or moist, thick and dirty yellow fur, and clean, red edge and tip of the tongue—the super-orbital pain—the rachialgia—the single febrile paroxysm, and its sudden cessation at the end of some forty to seventy-two hours, more or less—the absence, from that period, of all fever—the progressive increase in the slowness and depression of the pulse—the gradual loss of cutaneous heat—the albuminosity of the urine—all these may be viewed, in their *ensemble*, as typical of the disease, and as its characteristic and pathognomonic phenomena. When they all occur together, or when only one or two fail to do so, the physician may be assured he has to deal with the yellow fever; and the certainty is enhanced when the case in which they are observed presents itself at a period of the year, and under circumstances favourable to the development of the disease. On the other hand, when they are all, or for the most part, absent—the black vomit and jaundice particularly—we may, in the majority of cases,

safely conclude that the disease is of a different kind, even when circumstances are favourable to the development of the yellow fever cause.

The prognosis in yellow fever is upon the whole unfavourable — under ordinary circumstances, and with the exception only of some epidemics of unusual mildness, the disease is of the most dangerous character, and the chances of recovery are slender. But little aid is afforded in enabling us to arrive at a correct prognosis by the presence or absence of signs which in other diseases are of the highest value. Cases occur in which, when everything would seem to indicate a favourable result, the patient has been carried off with great rapidity, while on the other hand, cases of recovery happen in which, from the nature of the symptoms, a fatal termination might naturally have been anticipated.

According to Dr. Blair, (*op. citat.*) a slow pulse and moderate temperature of the body, and quiet stomach, are always favourable indications. But the more fiery crimson the tip and edge of the tongue, the more irritable the stomach, the severer the headache, the worse the prognosis of the first stage, and *vice versâ*. Slight or moderate epistaxis is a sign of little prognostic value in any stage; but streaks of blood in the early vomit indicates much danger, while, during the stage of black vomit, or after an elimination has set in, it is a favourable appearance, provided the blood corpuscles are found entire. In the second stage, the earlier or more complete the suppression of urine, and the more copious the ejection of black vomit, the more imminent the danger. But if the urinary secretion continue, and the black vomit be scanty from the first, or is afterwards suppressed, the patient may yet survive. Urine simply albuminous is a less serious sign than when it also contains tube casts; but if the latter are thin and few in number, they do not add much to the gravity of the indication. Free, copious urine, no matter how dark or bilious, is the most favourable of any single sign. If the urine be scanty, and, at the same time, loaded with tube casts, entangled in epithelial and fibrinous matter, forming a light, buff-colored sediment, it indicates a complex lesion of the secreting structure of the kidney, and is as fatal a symptom as entire suppression. Blood corpuscles in the urine are not a bad indication. A faltering of the articulation is a bad prognostic, still more so when attended with a difficulty of protruding the tongue. The danger of the attack is enhanced by its inflammatory complications, and by hypertrophy of the heart. The recency of residence in a cold or temperate climate — the race or complexion of the individual — his age, habits of life, and preceding condition of health — and the fact of his having already suffered from an attack of the disease, are all to be taken into consideration in judging of the chances of a favourable recovery.

Dr. La Roche has presented in detail, and at great length, the various phenomena, the absence or occurrence of which in a case of yellow fever may be considered as favourable or unfavourable indications, and to the work of that gentleman we must refer for an account of all that the most accurate and repeated observations have taught us in reference to the prognosis of the disease. In the meantime we borrow from him the following general remarks:

1. As the yellow fever is more or less modified as to the degree of its prevalence, the severity of its attack, and the mortality it occasions, by certain peculiarities connected with the condition and habits of the patient, his age, sex, race, constitution, idiosyncrasy, &c.; it follows as a necessary consequence, that when it occurs under circumstances the least favourable in the above respects, the prognosis will be equally unfavourable.

Hence, we need not fear so much the issue in children, females, negroes, or those who have already passed through the ordeal of the disease, in natives of the warmer latitudes, or in those whose habits are temperate; while youth, a plethoric state, a sanguine constitution, high living, and intemperance, predispose to, while a debauch, excessive fatigue, or terror, a fit of anger, the intemperate use of venery, &c., often excite a severe attack, from which the chances of recovery are less to be anticipated.

Generally speaking, the more recently a stranger has arrived the more severe the attack. The same may be said of the remote cause itself, which, in some seasons, is of such a degree of malignancy as to produce a disease, which, though apparently differing little from that of other periods, has a greater tendency to end fatally, and must, therefore, call for a very different prognosis. Again, the latter must be more guarded during the continuance of the same epidemic in different parts of an infected

city—the symptoms appearing the same—inasmuch as the malignancy and fatal tendency of the fever differ in them. The same remark is applicable to the several periods of the same epidemic. In general the prognosis should be more guarded at the outset, as the disease is more apt then to terminate fatally.

2. As a general rule, it may be said, that in yellow fever it is not so much the presence of good signs which we are to look for in order to form a favourable prognosis, as the absence of bad signs. What would be regarded as good signs in most other diseases, are of little or no avail in this, and many patients recover after exhibiting some one or more of those which experience, in many fatal cases, teaches us to look upon with suspicion. Nevertheless, the appearance of any one of the decidedly bad signs, and still more a combination of them, must be viewed with fear, leading, as they very generally do, to a fatal termination.

3. It is not less to be noted, that much more is to be expected from a gradual amendment of the febrile and other symptoms than from a sudden disappearance of even the most unfavourable of these. From the latter change, indeed, the most disastrous results may in general be expected—followed, as it generally is, by delirium, coma, and other bad symptoms. The danger of the disease, great as it is, when uncomplicated with any other complaint, becomes much more so, and calls for a more unfavourable prognosis, when to the phenomena which reveal its existence, are superadded those indicating the coexistence of other disorders.

4. With the exception of the mildest or ephemeral forms of the disease, the danger to be apprehended is, generally speaking, proportionate to the shortness and rapidity of the case. When the disease extends to the seventh, ninth, or eleventh day, recovery may reasonably be expected. The same favourable view may be taken from the prolonged duration of the stage of reaction—the danger in the subsequent stage being proportioned to the shortness of the first, and the early supervention of the state of metaptoxis.

5. In cases marked by decided remissions, the disease, as we have seen, is of a milder character, and admits, therefore, of a much more favourable prognosis, however severe the febrile reaction may be during the exacerbation.

6. Rigors, at the commencement of the attack, denote considerable danger, and are usually viewed as signs of fearful omen, the danger being proportionate to their duration. The same may be said of chills, when violent, long continued, and repeated.

7. Considered in a general way, the yellow discoloration of the skin, which has given a name to the disease, is doubtless a sign of importance in a prognostic point of view; for, though not invariably observed in all fatal cases, it is much more frequently seen in these than in cases of recovery. Hence, generally speaking, the appearance of this symptom must be regarded with suspicion.

The appearance of jaundice at an early period of the disease may be viewed as a symptom of serious import, and as indicating an attack of a dangerous, and even fatal character—the danger increasing in proportion to the deepness of the discolouration. When, on the contrary, it appears at a late period—after the sixth or seventh day—it is of dangerous import, and may even be said to assume the character of a critical sign. As regards the peculiar hue it presents: in many cases, and during certain epidemics, the light yellow or lemon colour has proved more dangerous than the dark yellow; while in other seasons and localities, the reverse is said to have been the case. Jaundice is indicative of more danger when it assumes a greenish, violet, mahogany, or bronze hue, and particularly when the skin presents a mottled or party-coloured appearance, characterized by livid, olive, and ash-coloured patches of all sizes, and blending into each other. Greater apprehension is to be felt when the discolouration in question is rapidly and very extensively diffused over the body, than when it is limited in extent, and spreads slowly. (See *La Roche, opera citat.*)

In proceeding to a consideration of the treatment of yellow fever, we may remark, that this must be based upon the character assumed by the disease in its different visitations, and even in each separate case that presents itself. The same therapeutical measures are not adapted alike to the inflammatory and to the congestive forms of the fever. Nor will the same course of treatment tend to conduct to a favourable termination of those cases, in which, from the very onset, the disease assumes an unquestionably malignant or deadly aspect, and those the symptoms of which are so mild, that recovery will be spontaneously, or with but slight aid from medicine—while it will be

as little adapted to the cases intermediate between these two extremes—where the object of the physician should be to apply in time those means best calculated to produce a favourable impression on the train of morbid actions, and thereby arrest their dangerous tendencies.

The treatment of yellow fever must be modified according to a variety of circumstances. As remarked by Dr. La Roche, *op. cit.*, “in encountering this formidable disease, we must content ourselves with endeavouring, not to neutralize the poison circulating in the system, but to correct the morbid effects it occasions on both solids and fluids. We must, while watching carefully the course of the disease, prevent undue mischief from being done, especially to organs essential to life. We must keep these organs in as healthy a condition as possible—restore, if possible, equilibrium in the play of the functions—reduce undue and dangerous excitement, general and local, and sustain the powers of life when these threaten to become impaired, or are already reduced beyond the point of safety. But we are forced to confess that, beyond this, art is of little avail. The idea of *curing* the disease, or greatly abridging its course, is entitled to little confidence. To nature must be left the chief management of the case; time must be allowed for the elimination of the poison; and the physician must be impressed with the conviction that, in cases where no marked organic mischief has been done, or is likely to occur, he must keep his hands off as much as possible, and restrict his agency to the employment only of such means as are strictly necessary to fulfil particular indications. He must not attempt to do what is more safely done by the recuperative powers of the system, and rest assured that in these and indeed in all instances, more danger is to be apprehended from too great than too little interference on the part of the medical attendant.”

When called to a case of yellow fever, a primary object of solicitude on the part of the physician, should be, to guard as much as possible against all disturbing influences. He must see that the patient is confined effectually to his bed, and prevented from rising. He must give proper directions for the free ventilation of the apartment, and the preservation of cleanliness; while, whatever be the form the disease assumes, he should proceed to the medical treatment of the case with the least delay possible. The great rapidity with which the dangerous symptoms make their appearance, the little time afforded for preventing their onset, and the great importance of effecting that object—besides the difficulty of their removal when they do appear—render such promptness imperative. At the same time, a knowledge of the insidious and treacherous nature of the disease, the great difficulty of predicting whether symptoms indicative generally of a mild attack are not soon to be succeeded by those of an opposite kind, and whether changes calculated to make us hope for a favourable issue are not to be followed—perhaps in a few hours—by others portending approaching death, should make him constantly attentive to the nature and succession of every phenomenon.

Attention being paid to these details, the medical treatment will necessarily vary according to the particular form which the disease assumes. In the several varieties of the inflammatory form, recourse must be had to antiphlogistics, sedatives, and evacuates, graduating the energy of these to the degree of the violence of the reaction, the force of the circulation, the heat of the skin, and the extent of the local inflammations or congestions. Of the indispensable necessity of antiphlogistic and evacuating treatment, which in this, as in other fevers of kindred nature, consists in sanguine evacuations, sedatives—internal and external—and purgatives, there can be no doubt. It is based on the evident character of the complaint, and the success which has attended its application, and comes to us under the sanction of innumerable and high authorities.

The foregoing remarks apply exclusively to the first stage of the inflammatory form of the disease. To be productive of benefit the remedies indicated must be resorted to without loss of time—their success being proportionate to the earliness of their application. They are not, it is also to be recollected, as a general rule, to be used with the same freedom as in ordinary inflammations. Except when there is inordinately high reaction—or when important organs are seriously inflamed or congested, and the patient is vigorous, plethoric, and young, and the recuperative powers of the system energetic, it would be safer to avoid the use of agents calculated to debilitate suddenly and considerably, and to trust to milder means. While endeavouring to

relieve inflammation or congestion, we should never lose sight of the imperative necessity of husbanding the strength of the patient, and of avoiding everything calculated to depress the powers of life and foster the tendency to collapse.

While general excitement, local inflammations and congestions, if they exist, are reduced by suitable depletion and sedatives, and the bowels, when costive, opened by mercurial and other purgatives, attention must be paid to tranquillize the stomach—and the physician must watch the efforts of nature, and promote any critical movement she may indicate.

Various means have been proposed and recommended to calm the stomach. Lecches or cups to the epigastrium in cases where they are admissible, have, occasionally, been found beneficial. Lime water by itself, or combined with an equal quantity, or two-thirds of new milk, in doses of a wine-glassful, has been highly recommended; other means have been also used with more or less success.

Among these may be enumerated the carbonates of soda and potass, the saline mixture, the effervescent draught, yeast, calcined magnesia, porter, chalk mixture, liquor potassa in barley water, carbonate of ammonia and hydriodate of potassium, and spruce beer and essences. Of all remedies of the alkaline class, the chlorate of potass is entitled to most notice in this place, from the praise it has recently received from the high authority of Professor Frost, of Charleston.

The nitrate of silver—small doses of creasote diffused in water—chloroform, in doses to the extent of even half a drachm, have likewise been recommended—they would all appear to us to be of doubtful propriety in the first stage at least of inflammatory cases.

After the more decided inflammatory symptoms have been subdued, turpentine, combined with a portion of mucilage, in doses of ten drops every two hours, will often be found very speedily to check vomiting—under the same circumstances also, a blister or sinapism over the epigastrium will be found of service. The acetate of lead, in doses of from grs. $2\frac{1}{2}$ or 3, every three or four hours, either in pills or simple solution, has been highly recommended, and will sometimes succeed in restraining the frequent retching and violent vomiting so characteristic of the disease. When we have succeeded in checking the violence of the fever, and in relieving whatever local irritation or congestion may be present, and an intermission has been obtained, “or,” to use the language of Dr. La Roche, “when the latter or metaptoxis has occurred at the regular time by the spontaneous subsidence of the febrile excitement, little remains to be done beyond keeping up the strength of the patient by mild tonics and light nourishment, and preventing, if possible, the onset of further and malignant symptoms, by the use of antiperiodic, tonic, and astringent remedies. But when the remission is incomplete, or is succeeded by a train of symptoms indicating a continuance and exasperation of the disease, another and different course must be pursued. The irritability of the stomach and the vomiting, as also the inflammation of that organ, if it occur, must be combated by sedatives and antacids internally, emollients and revulsives externally; the cerebral organs, if implicated, must be attended to, and their irritation or congestion treated by ordinary means; the failing powers of the system must be sustained by nourishment, tonics, and stimuli, either by the stomach, if it will bear them, or, in the contrary event, by the rectum; while the hæmorrhagic tendency must be arrested by astringents or other suitable remedies.

In the congestive form of the disease, when the reaction is deficient or altogether wanting, recourse must be had to means calculated to arouse and sustain the dormant energies of the system, and, at the same time, to relieve the sufferings of the overloaded organs. External stimulation, by means of rubefacients, hot baths, sinapisms, vesicatories, &c.; the internal use of stimuli, tonics, &c., by the stomach or bowels, and, in the milder cases, stimulating and mercurial cathartics, must be resorted to; and, whenever it can be done with safety, the congested vessels of important organs, and the inflammation of particular parts, which sometimes is combined with the congestion of others, must be relieved by general and topical bleeding.

Local depletion, by cups or leeches, may be resorted to in many cases of yellow fever, where general depletion is not considered advisable; or for the relief of particular organs. The cups or leeches should be applied as near as possible to the part affected—on the epigastrium, when the stomach is to be relieved; on the temples,

along the course of the jugular veins, inside the nostrils, or at the back of the neck, when the condition of the encephalon calls for assistance. As a general rule, local depletion should be resorted to at as early a period of the disease as possible. When practised late, it is of no utility, and may even act disadvantageously, by increasing the prostration of the powers of life.

Sudorifics are strongly recommended by many in the treatment of yellow fever in its earliest stage. The warm and vapour baths, or pediluvia of warm water, or warm water with mustard, aided by warm lemonade, or a warm infusion of some agreeable vegetable substance, have unquestionably been found, in many cases, when properly timed, to produce a general diaphoresis, from which very decided relief has been obtained. It is only at the very onset of the milder cases, however, that much benefit is to be expected from these sudorifics. In the more decidedly inflammatory forms, they cannot fail to prove prejudicial. From the irritable state of the stomach, there is little to be expected from the usual diaphoretics internally administered.

The warm bath is particularly appropriate when, in the early stage, the reaction is imperfect, partial, or deficient—when, in a word, the disease assumes one of the grades of the congestive form. In such cases, a general bath of high temperature—not less than 100°—will tend to promote a return of heat to the surface, and diffuse it if unequally distributed, and at the same time revive the activity of the circulation. In general, the water may be used alone; but in the case of extreme collapse, its beneficial effects will be greatly enhanced by the addition of salt, spirits, or mustard.

There are a number of means which may be resorted to, in order to meet particular indications—to relieve pain and local inflammation. Pediluvia, warm or tepid, fomentations and cataplasms are generally used, and found useful. Warm frictions, either dry or with soap, with hot oil, whiskey, or stimulating lotions, or, again, with lemon juice, will also find a useful application. The latter means—frictions with lemon juice—constitute a main instrument of what is called the creole treatment, or that of the colored women of the West Indies, and is favourably spoken of by the medical writers of experience in tropical climates and this country.

In the early period of the first stage of the fever, when the skin is hot and dry, cold water, applied over a considerable extent of the surface, either by sponging or affusion, has been found, at times, to exercise a beneficial influence, and by many physicians, is considered an important agent in the treatment of the disease. Such has been the case in tropical climates, and the results there obtained will be found fully corroborated by those recorded in temperate latitudes.

Dr. Blair remarks, that when the heat of surface was ardent, the *wet sheet* or *blanket* was used for the reduction of temperature by evaporation, with frequently very good effect.

The same rule must be observed in the application of cold water in cases of yellow fever, as in other febrile diseases—namely, it should be resorted to, only when the skin is decidedly hot and dry, and the reaction well established. Under such a condition of things the application of the cold water is usually followed by a reduction of heat and of vascular action, as well as, also, in numerous cases, by a tendency to perspiration, a sensation of comfort, and an abatement of many unpleasant symptoms. The same effects, but in a less degree, will result from partial applications of cold water or cold pediluvia. When applied, on the contrary, under other circumstances, very opposite results will very generally follow.

“If,” as Dr. La Roche well remarks, “the skin be cool and the pulse depressed, the sedative effect of cold water will have a tendency to aggravate the symptoms. Reaction, in such cases, seldom occurs; the disease becomes more concentrated within the internal and important organs, and the prostration of the vital powers increases rapidly. When the skin, instead of being dry, is warm, moist, and relaxed—which, as seen, occurs sometimes in all epidemics, and very generally in others—the application of cold to the surface has a tendency to check the salutary condition, and will almost always sorely aggravate instead of benefiting the disease. Nor are cold ablutions to be less avoided when the patient complains of chilliness or dyspnoea; or when he labours under diarrhoea, or deep congestion, or well-marked inflammation of internal organs; or, again, when he is of weak constitution or of advanced age.”

“In cases attended with a moderate degree of temperature of the surface; or when, after depletion, or without, the skin exhibits a tendency to perspiration; when, again,

the patient suffers from restlessness or other nervous symptoms, or when the shock from cold water is unpleasant, the tepid bath, or ablation with water of slightly elevated temperature, or a sheet dipped in tepid water, is found highly advantageous."

"In cases in which it is inconvenient or improper, for particular reasons, to have recourse to the hot or tepid bath—general or partial—the effect will often be obtained by means of the artificial vapor-bath, obtained by pouring water, either alone or mixed with vinegar, on hot bricks and introduced under the bed clothes."

It is scarcely necessary to point out the importance of placing the patient in apartments, large, clean, dry, and well ventilated, and so situated as to secure for him the advantages of pure, cool, fresh air. Under all the circumstances of the disease, let whatever be its form, this is an all-important measure.

The drinks of the patient should be cool and refreshing—in the first stage of the inflammatory form of yellow fever, cold water is perhaps the best, taking care, however, that it be taken in moderate draughts, at short intervals, to avoid over distension or prostration of the stomach. Where the stomach is irritable, and bears with difficulty the ingestion of water or other cool liquids, small portions of ice, held in the mouth and slowly swallowed, will often prove highly refreshing.

A variety of drinks have been suggested, and in many cases may be resorted to with advantage, as weak lemonade or orangeade, tamarind, currant jelly, and raw-apple water; thin flaxseed, or gum water, plain or sweetened; iced carbonic acid water. "Under the use of cold and iced drinks, the irritation of the gastric mucous membrane," remarks Dr. La Roche, "often subsides; the sense of heat and ardour at the epigastrium; the nausea and vomiting; gastric hæmorrhage, as well as the general excitement of the heart and arterial system, diminish; while the temperature of the skin is apt to lessen, and a disposition to perspiration not unfrequently manifests itself.

When the mucous surfaces, as indicated by the tongue, were denuded of epithelium, we are informed by Dr. Blair, that the use of gum water was found decidedly beneficial, by its lubricating, defending, and soothing the raw surfaces. In general, three drachms of the purest powdered gum were dissolved in six ounces of cold water, of which a tablespoonful was given every hour or two. For thirty-six or forty-eight hours of the most critical period of the disease, the patient will take it without dissatisfaction; after that, it can be substituted by, or alternated with, arrow-root pap.

In all cases—even in those characterized by considerable thirst—care must be taken not to overload the stomach, as nausea and vomiting will almost inevitably be the result. The preferable plan is to direct the patient to drink often, and to take but a very small quantity at a time. Even in cases unattended with much thirst or irritability of the stomach, it is proper to enjoin the same rule of frequent and moderate drinking, for the double purpose of soothing the irritation of that organ, and guarding against awakening a disposition to nausea and vomiting, which, as we have seen, are almost constant attendants on the disease, and require but a trifling cause to bring them on.

Dr. Blair found a dislike of sweets in yellow fever patients, and when lemonade was asked for, the usual quantity of sugar was objected to. Tea was found uniformly to disagree with the patients, and to cause vomiting, particularly in the advanced stages.

In cases characterized by symptoms different from those enumerated, the drinks should be of a higher temperature; and where there exists a tendency to perspiration, they should, the condition of the stomach allowing, be taken warm and slightly aromatized.

In an advanced stage of the disease—when the powers of life are fading, the drinks should be of a stimulating and nourishing kind. Porter and water, weak punch, weak wine-whey, claret, champagne, or hock wine, brandy and water, &c.

When the gastric irritability is so great as to forbid the admission of any thing into it, much benefit is often derived from the use of small and strongly purgative enemata. They act on the principle of revulsion—excite the peristaltic action of the tube downwards, and thus tend to quiet the stomach. In the advanced stage of the disease, especially when the stomach rejects every thing, stimulating and tonic substances introduced by means of injections, sometimes prove serviceable.

Blistering is not admissible in the early stage of the inflammatory form of yellow fever. At the commencement of the second stage—when symptoms of an unfavourable character are present, blisters to the ankles and other parts will often produce a favourable revulsive action, or prevent the depression of the vital powers. At a later period of the disease, when symptoms of prostration present themselves, blisters, in conjunction with other stimulants and excitants, will not unfrequently contribute in arousing the sinking energies of the system.

In the early period of the congestive form of yellow fever, blisters are adapted to aid in the restoration of action to the surface of the body, and in the excitation of the general circulation and nervous system. They will, also, often prove serviceable for the relief of gastric distress, pain, nausea, and vomiting, in cases of the disease where the febrile excitement does not run high, or in its second stage, when applied to the epigastrium or spine; they will, likewise, not unfrequently be decidedly beneficial for the relief of the headache, delirium, and stupor, attendant on the various stages of the disease, when applied to the nape of the neck, to the occiput, or to the upper extremities. So, in like manner, pain in the region of the thorax, whether resulting from disease of the lungs or external muscles, as well as the tormenting rachialgia, will sometimes be relieved by blisters to the affected parts.

In order to obtain the effect desired from the application of a blister; it is not always necessary to produce vesication. By removing them so soon as they have produced a rubefacient effect, a revulsive action is obtained without risk of gangrene, soreness, or hæmorrhage, while the effect may be renewed when it subsides too soon.

Sinapisms may, in many cases, be usefully substituted for blisters, and should always be preferred when the urgency of the symptoms calls for a prompt and energetic treatment. They are particularly useful to tranquillize the stomach, and remove local pain; and, in congestive, as well as in the advanced stages of ordinary cases, to invite excitement to the surface, and arouse the failing power of the nervous and arterial systems. By some they are used early to counteract congestion.

While all internal stimulants are strongly contra-indicated in the first stage of the inflammatory form of yellow fever, they are sometimes required in cases in which from the onset the reaction is feeble and deficient—in some of the modifications of the congestive variety—to arouse the energies of the vascular and nervous systems—even when bleeding and other means of depletion are employed to empty the congested organs. In not a few cases, however, of even the congestive form of yellow fever, the early use of stimulants is unnecessary and improper. It is chiefly in the advanced or sinking stage of the disease that they are admissible; and they are here often required in very large doses. They are sometimes instrumental in sustaining the powers of life or mitigating particular symptoms, and thereby enabling the patient to outlive the disease.

Nearly all the articles included in the class of stimulants have been recommended, capsicum, serpentaria, wine, brandy, ammonia, camphor, chloride of sodium, sulphuric ether, spirits of turpentine, etc. No one of these can be considered as specifically adapted to the disease; all have no doubt been found useful, and it is equally certain that all have equally failed.

According to Dr. Blair the employment of ether was frequently found to be attended with marked advantage in removing or abating the distressing symptom, hiccup. It was also used as a diffusible stimulant, and when acceptable to the patient, he pronounces it fully equal for that purpose to brandy.

Opium, which is admissible, at an early period of the disease, only in the decidedly congestive form, when stimulating means are required to rouse the prostrated powers of life, has been recommended, in the latter stage of ordinary cases to support the system—and, in combination with the other stimulants may, sometimes, be found useful.

At this particular stage the cinchona bark, quinia, and the tincture of the hydrochlorate of iron, have been recommended as tonics.

The Peruvian bark, which has been suggested by some as an appropriate remedy even at the very onset of the fever, and by others at the close of the first stage or during the remission, is now, we believe, very generally considered as useless, or even mischievous, except during the last or sinking stage, when, probably, it may sometimes do good as well by its tonic as its astringent properties. Of the sulphate

of quinia, which has supplanted the bark as a therapeutic agent, the same remarks may be made.

Of late years the quinia has been recommended at the very onset of the attack, in large doses, with the view of at once cutting short the disease. In reference to the success of this abortive treatment of yellow fever, as it has been termed, we have been favoured with much discordant testimony, but none which, in our estimation, are of sufficient weight and clearness to recommend it strongly to our notice.

It would, nevertheless, be unfair not to refer to the strong testimony recently presented in its favour by Dr. Blair. In the course of the epidemic which occurred in British Guiana in 1852 and '53, the primary object of treatment was, he states, to abort, if possible, the attack by the administration of a mixture of calomel and quinia. Twenty grains of the first, and twenty-four of the second, for an adult, given in some simple syrup. The same being repeated at intervals of four or six hours, to the extent of four doses, unless the attack was earlier arrested. If, he remarks, after three or four doses are given the disease is not cut short, little room is left for active interference on the part of the physician, although still much may be done in putting the patient in the best condition for sustaining the struggle, and keeping off intruding complications.

The aborting dose of calomel and quinia, we are told, should be used as early as possible in the attack. When a state of apyrexia is induced, it may be relinquished—the end is attained; but, if the urine has become coagulable, or the epithelium of the tongue has begun to peel, it is of no use pushing it further, the time for its use has passed, and subsequent to this it will be a noxious irritant.

Sometimes, Dr. Bailey remarks, the disease is incompletely aborted, that is, although it does not proceed to the second stage, a certain amount of febrile action still continues after the abortant has been pushed to a reasonable extent. It was the practice then to give half an ounce of camphor water and spirit of mindererus every three or four hours, till the skin became cool and soft. Should, however, the stage of acid elimination supervene, this medicine is stopped, and small doses of bicarbonate of soda and nitre (five to ten grains of each) substituted.

In preparing the irritable stomach for the reception of the abortive dose of calomel and quinia, creasote, is stated by Dr. Blair, to have had often an admirable effect.

The muriated tincture of iron comes to us with such strong testimony in its favour, as a remedy adapted to even the earlier stages of yellow fever, that it demands a further trial.

We have said nothing as yet of the mercurial treatment of yellow fever, so highly lauded for its superior efficacy by several physicians of high repute. It does not appear to us that any evidence has been adduced to prove that this plan of treatment has been more successful than others; while from the known effects of the mercury upon the blood, we should apprehend an increase of the very morbid condition of that fluid, which, from an early period of the attack, constitutes so prominent a feature of yellow fever. From these considerations, and the uncertainty of our being able to place the system under its specific effects—the probable failure, even when obtained, of their producing the desired result, and the time lost in waiting for those effects to develop themselves, we should be inclined to reject mercury from the list of the therapeutic agents adapted to the disease.

In the management of a case of yellow fever, more perhaps than in one of any other disease, is it important to remove from the patient all impressions of a moral kind—to keep up his spirits and sustain his courage. His alarm and anxiety for the result of his case must, by every means, if possible, be quelled, and the stimulus of hope constantly kept alive; unless this be done—remedies are of little avail.

In the early stage of the inflammatory form of the disease, total abstinence from food should be enjoined, or only thin gum, rice, barley, or apple water allowed; or in the milder cases, arrow-root, sago, Indian, or oat-meal gruel, or the like, may be allowed in small quantities, and at reasonable intervals.

When the activity of the pulse has been reduced, and the skin softens and loses its excess of temperature; when the gastric irritation lessens also, and especially when the stage of metaptoxis sets in with fair prospects of increasing amendment, the diet should be made more nourishing.

Animal food, whether in the form of soup, carefully freed from fat, or in substance,

may be given, but with great circumspection; it may even be better to restrict the patient to farinaceous and vegetable articles. Thin rice and bread cream, arrow-root, sago, Indian mush, oat-meal gruel, slightly sweetened and aromatized, thin panada, weak coffee, tea, or chocolate, milk and barley-water, answer well, when given in small quantities at a time, and at short intervals. They are better suited than animal food to the existing condition of the digestive powers, which are often considerably impaired.

Wine, and other spirituous liquors, except when the debility is unduly prominent, and all signs of inflammatory irritation have subsided, must be avoided as unnecessary and often hurtful. Considerable attention is also required as to the quantity in which food is allowed — much mischief is often done by the patient indulging largely in even the most bland and proper articles. As a general rule, it is safer to give but a small portion of nourishment at a time, and gradually to increase the quantity.

As febrile irritation and gastric irritability further subside, and the favourable crisis approaches, the food must be given at shorter intervals, and rendered more nourishing. It may now consist of the same articles prepared in a more generous manner, or of milk, stewed fruit, chicken or veal broth. When the debility is considerable, beef-tea, animal jelly, &c., may be allowed. This choice of aliments, graduated in the way mentioned, to the condition of the digestive powers and of the system at large, must be persevered in to the period of convalescence. It is equally well suited when the disease, instead of progressively subsiding without the occurrence of bad symptoms, passes to the third stage, or that of depression. When, however, the disease assumes a malignant character, and symptoms of positive prostration call for tonics and stimulants, nourishing food, in the form of strong broths, essence of beef, animal jellies, administered often and in small bulk, may be tried as long as the stomach remains quiet, and it has sometimes proved advantageous.

In congestive cases little or nothing can be done in the way of diet so long as reaction has not taken place. When reaction has been brought about, the diet must be regulated in the manner already adverted to.

During convalescence, while the use of the remedies employed in the preceding stage, is to be gradually diminished, the patient must be allowed more and better food, but the transition to the diet of health must be gradual, and care must be taken to select none but light and nutritious articles, and to avoid indulging in these frequently, and especially overloading the stomach. For some days, unless the debility be great, and all signs of gastric irritation completely subdued, the patient had better abstain from animal food, and limit himself to the use of eggs, bread, rice, bread and milk, panada, and oysters. As strength returns, and the functions of the stomach acquire energy, he may be allowed chicken, veal, mutton, or beef broths, prepared with a large proportion of rice, barley, and other vegetables. Poultry, game, and fish may follow; and finally, the more substantial meats may be allowed.

But necessary and indispensable as this gradual return to the diet of health undoubtedly is, the physician does not always find it possible to enforce compliance; for there is often such a sudden revival of the appetite for animal food at the commencement of convalescence that it is difficult to restrain the patient within proper bounds.

Cases not unfrequently occur, in which, from feebleness and languor of the stomach, or a state of general debility, mild, and even strong tonics and stimulants are called for. Under these circumstances, the infusion of bitter plants, of Peruvian bark, of serpentaria, or the sulphate of quinia, will prove serviceable; while malt liquors, wines — claret, sherry, madeira, hock — and even brandy and water, find a successful application.

Hæmorrhages occasionally occur during convalescence, which, as they indicate great debility of the system, and an atonic condition of the vessels, and tend to increase, by the loss of blood they occasion, the very cause on which they depend, must be checked with the least possible delay. In these cases, acids internally, and nitrate of silver, creasote, or the tincture of iron externally, cool air, as well as remedies calculated to impart tone to the system at large, are employed with advantage.

Quiet and cheerfulness of mind must be secured, and sleep must be encouraged. They are essential to a rapid and complete recovery. So long as debility is prominent, bodily exertions must be avoided; but, as soon as the strength admits of it, exercise, alternating with rest, and graduated to the condition of the patient — short,

and frequently repeated—must be enjoined. The venereal act—to which, convalescents are prone—should be carefully avoided, as always highly detrimental, and often, when indulged in to any excess, of fatal tendency.

Great stress must, at the same time, be laid on cleanliness and free ventilation, but more particularly on change of locality, and removal from the infected to a pure and cool atmosphere.

When circumstances will permit, and convalescence is long and tedious, a sea voyage, and a residence in a cold climate, must be recommended. — C.]

I pass, without pausing, from the consideration of continued fever, to that of *small-pox* or *variola*; a disease, fortunately, less common in this country than it used to be, yet still sufficiently frequent and formidable to require that we should acquaint ourselves with the phenomena it is accustomed to present; and very prevalent here, as it happens, at present (1838). I have already mentioned, by anticipation, several points in its history.

This frightful disease sets in with smart febrile symptoms: rigors, followed by heat and dryness of skin, a hard and frequent pulse, pain in the epigastrium, with nausea and vomiting, and headache. Sometimes wild delirium, sometimes convulsions, attend its outset. Then, to use the words of Cullen's definition, "*tertio die incipit, et quinto finitur, eruptio popularum phlegmonodearum, quæ spatio octo dierum, in suppurationem et in crustas demum abeunt, sæpe cicatrices depressas, sive foveolas, in cute relinquentes.*"

When small-pox is fully formed, it cannot be mistaken for any other complaint: but it is of some importance to recognise it at its very commencement, for the force of the impending disorder may sometimes be lessened by judicious measures adopted at that early stage. The symptoms, however, that mark the outset of all febrile diseases are necessarily very much the same. If the pyrexia set in when small-pox is prevalent in the neighbourhood, if the person in whom it occurs be an "unprotected" person (*i. e.* one who has neither had that disease, nor been vaccinated previously), and especially if he be known to have been exposed, within from nine or ten days to a fortnight, to the contagion of variola, we may well suspect that the disease will turn out to be small-pox, and act upon that suspicion.

Nevertheless there are some symptoms which, being common in the commencement of variola, and not common at the beginning of continued fever, or of the other exanthemata, may assist the early diagnosis. Vomiting is one of these; pain of the back another. When these symptoms are violent, they usually usher in a severe form of the disease. The same may be inferred from a continuance of the nausea and vomiting, after the coming out of the eruption; which is very unusual. Heberden noticed that acute pain in the loins was almost always followed by a severe disorder; that pain higher up, between the shoulders, was of better augury; and that it was to be reckoned in all cases a good sign, if there were no pain of the back at all. Early delirium, stupor, or convulsions, announce severity in the subsequent course of the malady. Yet not always, especially in children. Within the last month I was asked to see a child which had been suddenly attacked with convulsions, followed by coma. In due time the eruption of variola appeared, and the disease ran a mild course, with little aid from medicine, although the child was previously unprotected.

The peculiar eruption almost always begins to show itself on the third day of the fever. The earlier it comes, the severer generally does the disorder prove. In judging of the date of the eruption, you must bear in mind that parents and servants are apt to state its accession to have been later than it was in reality: for the spots are at first so minute that they often escape observation. They also frequently begin to come out in the night; and the morning of the second day of the eruption is then called erroneously the first day.

The eruption comes out first on the face, then on the neck and wrists and on the trunk of the body, and lastly on the lower extremities. Such is the rule; so that (as is specified in the definition) it does not cease to come out till the fifth day: and it keeps a-head, in that order, throughout the disease. There are, indeed, some exceptions to this rule. Occasionally the spots appear first upon the extremities, but this is very rare. In some instances straggling papulæ continue to spring up after the

main crop is fairly completed; but these stragglers seldom arrive at the same size with the others.

The pimples, or papulæ, ripen gradually into *pustules*, the suppuration being complete by their eighth day; and on that day the pustules generally begin to break, and crusts or scabs to form. In four or five days more the scabs are falling off. There are some variations in all this also. In children, the crusts are sometimes visible on the seventh day: and in adults, when the disease is severe, they sometimes do not begin to form till the ninth day. In all cases some of the pustules are liable to be prematurely broken, by accident, or by the patient's scratching; and these will crust over earlier than they otherwise would have done. So that in fixing the period of incrustation, you are to regard those pustules only, of which the natural progress has not been interfered with.

All that I have hitherto been saying, applies with more or less exactness, to the disease in all its varieties. But its severity differs exceedingly, as I have already hinted, in different cases. Its severity, in truth, is almost always in direct relation to the *quantity of the eruption*. The number of pustules indicates, in the first place, the quantity of the variolous poison which has been reproduced in the blood. In the second place, it is also a direct measure of the extent to which the skin suffers inflammation. Sometimes there are not more than half a dozen pustules; sometimes there are many thousands. If all these were collected into one, it would be an enormous phlegmon. For both these reasons the system suffers commotion, distress, and peril, in proportion to the quantity of the eruption.

When the pustules are very many, they run together: when they are few, they are separate from each other. And this affords a broad line of distinction, which can neither be overlooked nor mistaken, into the *variola discreta*, and the *variola confluenta*. In the one, the pustules are distinct, and of a regularly circumscribed circular form. In the other they coalesce, and their common outline becomes irregular. Now the discrete form of the disease is scarcely ever dangerous; the confluent form is never free from danger. The distinction therefore is of the highest importance and interest. For its full estimation, each form must be considered separately.

In the discrete variety, in which the disorder may be presumed to run its most natural course, the eruption is at first, according to the phraseology of Willan, *papular*. The pimples gradually increase in magnitude, but it is not till the third day of their appearance that they begin to contain a little fluid on their summits. For two days after this they increase in breadth only, and a depression is observable in the centre of many of them. The cuticle is bound down there somehow, for a time, to the cutis vera. It is the eighth day of the disease, or the fifth day of the eruption, before the pustules become perfectly turgid and hemispheroidal. During the time in which they are thus filling up, the face swells; often to so great a degree that the eyelids are closed; and the natural aspect suffers a complete and hideous change. The skin between the pustules on the face assumes a damask red colour. About the eighth day of the eruption, a dark spot makes its appearance on the top of each turgid pustule, and at that spot the cuticle breaks, a portion of the matter oozes out, and the pustule dries into a scab. When this crust at length falls off, it leaves behind it either a purplish red stain, which is still very characteristic of the disease, and which very slowly fades; or a depressed scar, which is indelible. In the latter case the patient, or more properly his skin, is said to be *pitted* with the small-pox, or pock-marked. The swelling of the face begins gradually to diminish after the eruption has become thoroughly pustular.

This is the course which the eruption pursues on the face, where the pustules, even in the discrete form of the disease, are usually thicker set than on any other part of the surface. And it pursues the same course, only two or three days later, upon the extremities, where it also begins later. The feet and hands swell just as the face swelled, but they begin to tumefy as the features begin to subside. Some of the pustules, especially on the extremities, do not burst at all, but shrivel up.

In this, the distinct variety of the disorder, the fever generally ceases entirely upon the coming out of the eruption: the headache, the pain of the back, the vomiting, the restlessness, abate and disappear, the pulse resumes its natural force and frequency, and the skin its natural temperature. About the seventh or eighth day of

the eruption there is commonly for a day or two a recurrence of fever. This is called the fever of maturation.

You are to observe that we judge of the eruption as it appears on the *face*. The disease is of the confluent kind, when the pustules are confluent there, whether they are so or not upon the trunk and extremities. Sometimes they are neither strictly confluent nor strictly separate, but stand just thick enough to touch each other, without absolutely coalescing; every pustule preserving its circular outline. In that case the disease is said to be of the *cohering* form. When the pustules are confluent over the whole body, their number is often prodigiously great, and their progress is less regular than in the discrete and milder variety of the complaint.

In the first place the eruptive fever itself is usually more violent and tumultuous in the confluent disease: the disturbance of the sensorial functions is more common and more decided, the sickness more distressing, the pain of the back and loins more severe. The eruption comes out earlier, and more confusedly; the pimples being at first very minute, and crowded together in patches, and not seldom accompanied by a rash like that of scarlet fever, or erysipelas: whereby the diagnosis, in so far as it depends upon the appearance of the skin, is rendered for a while uncertain. I have at present in the Middlesex Hospital a patient in whom the papulæ of small-pox were, at the outset, so intermingled with the appearances and sensations of urticaria, that I doubted, for twenty-four hours, what the true character of the eruption might be. It is sometimes like that of the measles; but the similarity and the uncertainty are soon at an end, for the pimples soon begin to exhibit a fluid on their summits. They do not, however, as they advance, and pass into pustules, fill up so completely as in the distinct form; they are flatter, less plump, more irregularly depressed, and even of a different colour; being at first whitish, and then of a brown tint, and seldom of the yellow purulent hue which is seen in the variola discreta. Sometimes they are even bluish, or purple. In the confluent form there is commonly some abatement of the febrile distress upon the coming out of the eruption, but the remission is much less decided than in the discrete. About the fifth or sixth day fresh rigors are apt to occur, marking the fever of maturation. Most of these points of distinction between the two varieties of the disease are well set forth in Cullen's definitions. The distinct form he defines thus: "*Variola (discreta) pustulis paucis, discretis circumscriptione circularibus, turgidis; febre, eruptione factâ, protinus cessante.*" And of the confluent kind his definition is, "*Variola (confluens) pustulis numerosis, confluentibus, circumscriptione irregularibus, flaccidis, parum elevatis; febre post eruptionem perstante.*"

But the most important difference between the two forms is in what is called the *secondary fever*, which sets in about the eleventh day of the disease, or the eighth of the eruption, just when the maturation of the pustules is complete, and they begin to desiccate. This secondary fever is slightly marked in the distinct small-pox, and very intense and perilous in most instances of the confluent. It is at this period of the disorder, that death, in the fatal cases, oftenest occurs. Of 168 such cases, recorded by Dr. Gregory, the deaths happened in twenty-seven (nearly one-sixth of the whole) upon the eighth day of the eruption. That, therefore, is the most perilous *day*, as the second is the most perilous *week*. Thirty-two died in the first week, ninety-nine in the second, twenty-one in the third. The early occurrence of death denotes a peculiar malignancy in the disease. The nervous system appears to be overwhelmed by the force of the poison. During the second week the disorder proves fatal chiefly in the way of apnoea; from some affection of the respiratory passages. After that period the characters of asthenia commonly predominate. The patient sinks under some casual complication, or the powers of life are gradually worn out by so much irritation of the surface, and so large an amount of suppuration.

So much for the ordinary course of small-pox, and of the symptoms that are essential to that disease. There are, however, other concomitant circumstances, with which you ought to be acquainted: and these I will endeavour to specify at our next assembling.

LECTURE LXXXVII.

Small-pox continued. Inoculation. Vaccination. Their comparative advantages. Treatment of Small-pox.

IN the last lecture I brought before you, in a rapid sketch, the ordinary course, and the essential symptoms of small-pox; both in its distinct and in its confluent form. I have yet to mention some other circumstances that are very frequently to be noticed in connexion with that disease.

Both kinds are accompanied by *sore throat*; the tonsils and fauces are tumid and red: and with this sore throat there is associated, about the period when the face swells, sometimes in the discrete variety, and almost always in the confluent, more or less *salivation*, which lasts for several days. At first the discharge is thin and plentiful: but, towards the period of maturation, it often becomes viscid and ropy, and is with difficulty got rid of by the patient. This salivation is of some importance as a *prognostic* symptom. If it cease abruptly, and especially if at the same time the swelling of the face suddenly and prematurely subside, the peril is great. Besides this, Sydenham regarded the *ptyalism* as a *diagnostic* circumstance; as a mark which identified with true small-pox a fever called by him the variolous fever, the *variola sine variolis* of De Haen and others. The resemblance (says he) which this fever bore, in its symptoms, to small-pox, induced me to give it the title of variolous fever, which seemed indeed so much the more appropriate, as the fever raged at the same time with small-pox, and got well under the same treatment. The two diseases belonged evidently to one family, and there was no difference between them, saving that in small-pox the morbid matter was directed towards the skin, in the shape of an eruption; while in the variolous fever this matter was expelled from the system by the salivary glands." Notwithstanding this statement, it is difficult to believe that any such disorder as *variola sine variolis* ever proceeds from the contagion of small-pox.

This affection of the salivary glands does not so often occur in children; but diarrhoea appears sometimes to take its place.

The soreness of the fauces often depends, in great measure, upon pustules there situate. You may see that the tongue, the roof of the mouth, the inside of the cheeks, the uvula, and the velum palati, are thickly studded with them. It is affirmed by some writers that the pustules of small-pox occur in various internal parts of the body, and especially upon the mucous membrane of the intestinal canal. I believe this to be a mistake. The enlarged solitary follicles often put on very much the appearance of pustules. Cotunnus, who has written a good book *De sedibus variorum*, asserts that pustules appear only upon the skin, and upon those parts of the mucous membranes which are freely exposed to the air. In one solitary instance he met with them in the trachea so low as its third ring. He fancied that previous desiccation of the part was necessary to their formation. He says that none appear on the cornea, while it is kept moist. He denies that they are seen in the interior of the body, or upon the foetus in utero: but in this last point he is certainly wrong; and this is a strong objection to his theory. The most striking facts which he alleges in support of his opinion of the necessary presence of air—besides the fact of the eruption being more copious on the parts usually exposed to the atmosphere, as the face and hands—are, that pustules do not form on the inner surface of the eyelids, except in cases of *ectropium*; that they appear on hæmorrhoidal tumours only when these project beyond the margin of the anus; and that that portion alone of the glans penis is ever affected by them which is uncovered by the prepuce.

Dr. Gregory, however, states that true variolous pustules do not form upon the conjunctival membrane: and that the blindness of one or both eyes, which is so common a result of small-pox, especially in children, is produced by an intense kind of ophthalmia, which sets in at the period of the secondary fever, and rapidly involves and spoils the transparent tissues of the organ.

During the period of maturation, a peculiar greasy, disagreeable odour, quite *sui*

generis, proceeds from the body of the patient. If taken into the sick chamber blindfolded, one might name the disease at once by the smell. About the same time also many patients are tormented by itching of the surface; so that they are provoked to scratch off the heads of the pustules; and by so doing they often ensure the formation of pits. In many cases of confluent small-pox this itching seems to constitute the chief part of the patient's suffering.

The various troublesome complications to which, in severe cases of the confluent form, the patients are liable during the secondary fever; erysipelatous inflammation involving the subcutaneous areolar tissue in various parts of the body, and leading to the formation of abscesses; glandular swellings in the groins and axillæ, going on sometimes to suppuration; sloughing sores on the hips and sacrum; phlebitis; and in two or three instances I have seen the large joints, after death, full of matter. One of the most serious symptoms, at this period of the disease, is dyspnœa. The air-passages, and especially the larynx, become clogged by viscid mucus, the arterialization of the blood is interfered with, and the patient is in danger of suffocation. Occasionally life is suddenly extinguished by œdema of the glottis, supervening upon that affection of the fauces which I mentioned just now.

In one most fearful phase of this always formidable disorder, symptoms indicative of what is called the putrid diathesis manifest themselves—*ptechiæ*, vibices, hæmorrhages from various parts of the body. The pustules, instead of being plump and yellow, are flat, red, purple, or blue; that is, they contain blood, or a sanious ichor, in the place of pus, constituting the *variola nigræ* of Sydenham, the *bloody* small-pox of Mead. I believe that these appearances augur in all cases a fatal result. Hæmorrhage from the uterus is not uncommon; and in pregnant women abortion, and then, most commonly, death. Heberden says that he examined, in many instances, the fœtuses so parted with, but never could perceive upon them any traces of small-pox. His experience, therefore, agreed with that of Contuinnius; and we may conclude that infection of the fœtus in utero is very rare. Yet, unquestionably, it sometimes happens; and the circumstances under which it has been noticed are various and interesting. In one instance, related by Mr. Flinders, the disorder was eight or ten days later in the fœtus than in the mother. A woman, near her full time, took small-pox. The pustules were mature about the 10th or 11th of June. On the 18th she gave birth to a full-grown boy, upon whose face and body there were many pustules, discrete, and nearly ripe. The child died the same night. It is a very curious fact that the fœtus had caught the disorder, doubtless through the medium of the mother, although she, having had it previously, was unaffected by the contagion. Dr. Mead relates that "a certain woman, who had formerly had the small-pox, and was now near her reckoning, attended her husband in this distemper. She went her full time, and was delivered of a dead child. It may be needless to add, that she did not catch it on this occasion; but the dead body of the infant was a horrid sight, being covered all over with pustules." In the first volume of the *Medico-Chirurgical Transactions*, Dr. Edward Jenner gives an account of an infant which, upon the fifth day of its age, became indisposed, and on the seventh exhibited the eruption of small-pox; so that the contagion must have been communicated to it while yet in the womb. A few days before her confinement the mother of this child had seen in the street a person covered with small-pox pustules, the smell and sight of whose body had sensibly affected her. I see no reason, therefore, for doubting that the unborn being may pass safely through the disease while in the womb, and derive from that attack the customary immunity for the future. My namesake, Sir William Watson, describes, in the *Philosophical Transactions*, an instance in which the scars left by the pustules were visible upon an infant at its birth. This child was afterwards inoculated without taking the disease. Its mother, who had formerly had it, nursed, when far advanced in pregnancy, a servant ill of small-pox. Dr. Pearson met with a similar example. Mary Spooner was inoculated by him in her sixth month of utero-gestation, and had the disease severely. Her child was twice inoculated with small-pox matter, but without effect.

Like all these contagious exanthemata, small-pox has its periods of dormancy, and its periods of activity. Every now and then, at irregular intervals—and, as it would seem to our ignorance of the cause, capriciously—it overspreads a district or country as an epidemic. At this moment (1838) it is more prevalent in London, and in

many parts of England, than it has been known to be for many years past. When epidemic, it is also, in general, more than ordinarily severe; although different epidemics vary much in that respect.¹

There is no contagion so strong and sure as that of small-pox: none that operates at so great a distance. Dr. Haygarth states, "that during his long attention to this subject, not a single instance had occurred to prove that persons liable to the small-pox could associate in the same chamber with a patient in the distemper, without receiving the infection." It is readily communicable in every way; by inoculation, by breathing a contaminated atmosphere, by the contact or vicinity of fomites. Nay, it may be caught from the dead body. Mr. Cæsar Hawkins has recorded an interesting example of this. The body of a man, who died of small-pox, was brought into his dissecting-room in Windmill Street; and four students took the disease from that source. Of these, one only had *touched* the body.

There is one appearance which I think curious, although perhaps it has not any great practical interest; and which I omitted to notice in the last lecture, when describing the course of the eruption. Without going minutely into the anatomy of the pustules, you may distinctly see, if you closely examine them when they are about five or six days old—you may see, at least in many of them—two colours, viz., a central whitish disk of lymph, set in, or surrounded by, a circle of yellower puriform matter. In truth, there is, in the centre, a *vesicle*, which is distinct from the pus. You may puncture the vesicle, and empty it of its contents, without letting out any of the pus; or you may puncture the part containing the pus, and let *that* out, without evacuating the contents of the vesicle. The vesicles have even, by careful dissection, been taken out entire; and they are said to consist of several little cells. It is most probable that the lymph contained in this separate vesicle is the purest part of the variolous poison.

Before I say anything of the measures to be adopted during the progress of small-pox, I have to bring under your notice two expedients of still greater interest and importance; the one of them contemplating a mitigation of the disorder, the other its total prevention. You anticipate that I am about to speak of *inoculated* small-pox in the first instance, and of the *vaccine disease* in the second.

I have many times stated, and all the world knows, that small-pox may be imparted to a healthy person by inserting beneath his cuticle a minute quantity of the matter taken from a variolous pustule. This, perhaps, is not very surprising; but it is surprising that the disease, so received, should be much milder than if it had been contracted in what is called the "natural way," by breathing an atmosphere charged with the contagious poison. Why it should be so it is difficult to conjecture. The fact is sometimes expressed by saying that the disease is milder when the virus is admitted through the cutaneous, than when through the mucous tissues. But I am not at all sure that the hypothesis involved in this proposition is true. No attempts have been made, that I know of, to introduce the poison artificially through a wound in any mucous surface. I should rather guess that the small quantity of the poison conveyed by inoculation into the blood may make the difference. But whatever the explanation, the fact is unquestionable, and obviously of the highest importance. By what accident it was first learned (for it evidently could not have been reasoned out) we do not know. The Chinese claim to have been in the habit for many centuries, of *sowing* the disorder, by putting some of the crusts into the nostrils. But this is a different thing from inoculation, the surface being entire, and the effluvia from the crusts being drawn into the lungs by the act of inspiration. It is said that a true engrafting of the virus has been in use by the Brahmans in India, time out of mind. It certainly was practised in Turkey at the very beginning of the last century, and perhaps somewhat earlier. In 1713, Dr. Emanuel Timoni, an Oxford graduate, who had settled at Constantinople, wrote to Dr. Woodward, in London, giving him an account of the new process, and testifying to its success. This account was communicated to the Royal Society, and published in its Transactions the following year.

¹ "In the present century there have been no fewer than six epidemics; the records of the Small-pox Hospital show that they occurred in the years 1825, 1838, 1841-45, 1848, 1851-52, and 1854-55-56. The last epidemic, which extended over parts of three years, was unusually severe as well as protracted, and reached its acme in May, 1855."—Report of the National Vaccine Board for 1857.

In 1715, Mr. Kennedy, an English surgeon who had travelled in Turkey, gave similar information to the English public in his *Essay on External Remedies*. And in the *Philosophical Transactions* for 1716 you may see a notice of the same process, as described by M. Pylarini, the Venetian consul at Smyrna. But these statements were neglected, or had no practical result. We owe the actual introduction of the practice of inoculation into Great Britain to the good sense and courage of an English lady, whose lively epistles have taken their permanent place in our country's literature. Lady Mary Wortley Montagu, the wife of our ambassador at the Ottoman Court, writes thus, from Adrianople, in the year 1718: "The small-pox, so fatal and so general amongst us, is here entirely harmless by the invention of *engrafting*, which is the term they give it. Every year thousands undergo the operation; and the French ambassador says, pleasantly, that they take the small-pox here by way of diversion, as they take the waters in other countries. There is no example of any one who has died in it; and you may believe I am well satisfied of the safety of this experiment, since I intend to try it on my dear little son. I am patriot enough to take pains to bring this useful invention into fashion in England." In fact, she recommended it by her own example. The first person inoculated with the small-pox in England was her daughter. Then a child of a physician, Dr. Keith, who had visited Miss Wortley; afterwards some condemned felons, who were pardoned on condition of their submitting to the experiment; and at length, some of the royal family. But the practice was not thoroughly established, nor properly appreciated, by the English public, until the middle of the century.

Its efficacy in mitigating the severity and danger of the disease, in saving life and preventing deformity, was signally great. The mortality in the natural small-pox was estimated at one in five. It is really higher. Mr. Marson infers, from the records of the Small-pox Hospital (where, however, the mortality is likely to be above the average) that the natural small-pox destroys about one-third of all whom it attacks.¹ But Baron Dimsdale, a great inoculator, declared that not one in fifteen hundred died of the engrafted disease. Two brothers, named Sutton, who had introduced, or rather revived, a very improved method of treating the disorder, professed to have inoculated 20,000 persons, without fairly losing one. But these, doubtless, were vastly exaggerated statements. Dr. Gregory says, "the average number of deaths at the Inoculation Hospital was only three in a thousand." The National Vaccine Board speaks decidedly of "one in three hundred" as the proportion of the inoculated that "will surely die" from the operation.

In the inoculated disease the period of incubation is comparatively short; the pustules are seldom numerous, and still more seldom confluent; and the secondary fever is generally slight or wanting.

I may mention here, also, that the eruption is not unfrequently preceded by a rash, something like that of scarlet fever, and called by Willan the *roseola variolosa*. It fades in the course of a day or two, and then the small-pox pustules are seen emerging just in the same state that they would have been in, at the same period, if no such rash had appeared. The efflorescence happens oftener in the inoculated than in the casual disease. In the former it is looked upon as rather a favourable sign; in the latter, especially if the rash be of a dark red colour, it is considered unfavourable, and as the herald of a severe confluent disorder.

A far superior expedient has since been discovered, in the practice of *vaccination*, which has rendered the inoculation of small-pox not merely unnecessary, but, in most cases, perfectly unjustifiable. Yet circumstances do sometimes arise, even now, in which it may be allowable and right to engraft the matter of small-pox; as when an unprotected person is unavoidably exposed, or has recently been exposed, to the contagion of that disease, and there is no vaccine matter at hand. The advantage of inoculating in such a case is, that the inoculated or milder form gets the start of the natural and severer; the fever commencing sooner than it would otherwise do. To show you the value of the practice in such cases, and the degree of protection which

¹ "Natural small-pox is a most fatal disease at all periods of life; the most so in infancy and advanced life; the least so from 10 to 15 years of age; under 5 years it is 50 per cent.; still greater, however, under 2 years; the mortality after the age of 20 rises suddenly, and increases gradually; at 20 it exceeds the mortality of infancy, and after 60 hardly any escape."—Marson, in *Med.-Chir. Trans.*

it affords to individuals whom we cannot vaccinate, I may mention a fact which Professor Gregory, of Edinburgh, was in the habit of relating, and which was told him by a naval surgeon. The small-pox was introduced among the crew of a man-of-war, in a tropical climate, where no vaccine matter was to be procured. The men were almost all unprotected. Sixteen of them took the disease in the natural way; and of these, nine, or more than one-half, died. Of 363 who were inoculated, under the disadvantages of a hot climate, and no preparation, not one perished.

That a disorder communicated to the human animal from one of the brutes should protect the former against the contagion of small-pox, is one of the most interesting facts in the whole history of medicine. How glimpses of a truth so remarkable were first revealed to the casual observation of certain peasants, and how the result of this chance observation was gradually "matured into a rational and scientific form by a mind deeply imbued with the best principles of sound philosophy," I have not leisure to tell you in detail. And it is the less necessary that I should do so, as you may find the whole subject thoroughly narrated and discussed by Dr. Baron, in his interesting biography of Edward Jenner.

Dr. Jenner found among the great dairy farms in Gloucestershire a popular belief that no person who had had the *cow-pox* (an eruptive vesicular complaint communicated from the udder of the cow to the hands of the milkers) could "take the small-pox." Satisfied, by inoculating with small-pox matter several individuals who had had the vaccine eruption, that this was not an unfounded notion, he at length conceived the great and happy idea of propagating the cow-pox from one human being to another, and so preventing, in all cases, the perilous and disfiguring distemper of small-pox, which he hoped might thus be finally expelled from the earth.

By degrees, Dr. Jenner ascertained that some persons, who had had sore hands from milking, were not thereby rendered proof against the contagion of small-pox; but this difficulty was soon cleared up by the discovery that the teats of cows were liable to different kinds of eruption, and he learned, by close observation, which of these was the peculiar eruption that produced in the human frame the protecting disorder.

Dr. Jenner set himself to trace, if possible, the origin of the disease of the cow. First, he found that it was peculiar to certain dairies; then, that in those dairies *men* were employed in milking. Following up this clue, he further made out that those men had also the charge of the farm-horses. Next, he learned that the teats of the cows generally began to exhibit the specific eruption at that time of the year when a complaint called "the grease" chiefly prevailed among the horses. Hence he concluded, that the malady was conveyed to the cows by the hands of the men who had been dressing the heels of horses affected with the grease. Subsequent inquiries have, however, shown that this conclusion was not strictly correct.

Another difficulty which lay in Dr. Jenner's way, and which his patience and sagacity surmounted, was this. He found that some who were casually infected from the true complaint in the cow were not protected. This depended, as he afterwards ascertained, upon the period of the disease in the cow, at which the virus was communicated to the milker. The thick matter proceeding from the vesicle late in its progress produced indeed a severer local sore than the thinner matter of its earlier state, but it did not confer the desired protection. The same thing is observed in respect of small-pox. If the matter used for inoculation be taken from a fully matured pustule, it does not so surely excite the disease as when taken from a more crude one.

The next important step in this most interesting investigation was to determine whether the vaccine disease could be transmitted, by engrafting, from one human being to another, and whether, if so transmitted, it retained its protecting power. The 14th of May, 1796, was the birthday of vaccination. "On that day, matter was taken from the hand of Sarah Nelmes, who had been infected by her master's cows, and inserted by two superficial incisions into the arms of James Phipps, a healthy boy of about eight years old. He went through the disease apparently in a regular and satisfactory manner; but the most agitating part of the trial still remained to be performed. It was needful to ascertain whether he was secure from the contagion of small-pox. This point, so full of anxiety to Dr. Jenner, was fairly

put to issue on the 1st of the following July. Variolous matter, immediately taken from a pustule, was carefully inserted by several incisions, but no disease followed."

It is scarcely necessary for me to notice the objections which were made to the practice of vaccination. Some of them were merely foolish—as, that it was unnatural and impious to engraft the diseases of a brute upon a Christian. Others were untrue—as, that it introduced into the system new, unheard of, and monstrous disorders, distinct from the cow-pox itself. It triumphed over all these cavils; and in six years from its first promulgation the discovery was known in every region of the world.

It was soon found, however, that some, who had apparently had the cow-pox by inoculation, were nevertheless not incapable of taking the small-pox; and that these failures were, many of them at least, attributable to the mistakes that were made in the time or manner of performing the operation. It became necessary, therefore, to ascertain precisely the conditions requisite for the production of the genuine disease. And these conditions have been successfully investigated by Dr. Jenner and by subsequent observers.

You will learn to recognize the true vaccine vesicle only by repeatedly examining it for yourselves. Yet a brief description of its characters and progressive changes may be useful to you.

On the second or third day after the insertion of the vaccine matter into the arm, the puncture looks red and inflamed; and on the fourth or fifth day the vesicle becomes perceptible; a pearl-coloured elevation of the cuticle enclosing a minute quantity of a thin transparent liquid. It gradually increases in magnitude till the eighth day, when it should measure from a quarter to half an inch across. Like the pustule of small-pox, it is more prominent at its circumference than at its centre, and it consists of small cells, from ten to fourteen in number. By puncturing carefully one of these cells, a drop of the virus may be let out, the other cells remaining full. Up to the seventh, or eighth, or even to the beginning of the ninth day, the inflammation around the vesicle should extend to only a very small distance from it. After this, it spreads, and what is called the *areola* is formed; a circular red border, which continues to increase during the ninth and tenth days, and begins to fade on the eleventh, passing through shades of blue as it declines, and leaving a degree of hardness behind for two or three days more. By this time, a brown or mahogany-coloured crust has formed over the vesicle, of a nearly circular shape; this becomes gradually harder and darker, and finally detaches itself about the twentieth day. The cicatrix which it leaves should be distinct, somewhat less than half an inch broad, circular, slightly depressed, marked (sometimes) by radiating lines, with a well-defined edge, and dotted with little pits which seem to correspond to the cells of the vesicle.

About the eighth day there is usually some slight febrile excitement manifested, which soon subsides. This is analogous to the secondary fever of small-pox: and it appears to furnish the condition of the desired protection.

Of course it is of much moment to determine whether the cow-pox has run its proper course or not; and it is not always easy to say how far the progress of the vesicle may deviate from that which has just been described, without failing of its protecting influence. A very ingenious *test* of this, free from all ambiguity, has been devised by Mr. Bryce. His plan is this. He vaccinates the other arm, or some other part of the body, four or five days after the first vaccination. If the constitution have been properly affected by the first operation, the inflammation of the second vesicle will proceed so much more rapidly than usual, that it will be at its height, and will decline and disappear, as early as that of the first: only the vesicle and its areola will be smaller. In fact, from the time of the formation of the areola, the second vesicle is an exact miniature of the first. If the system have not been duly influenced by the first vesicle, the second will run its own course, increasing up to its eighth day, and so on. Should this be the case, the second vesicle should be tested by a third.

We find the germ of this criterion in the early history of vaccination. Dr. Jenner vaccinated the children of his friend, Mr. Hicks, the first *gentleman* who consented to adopt the practice. This Mr. Hicks became afterwards an expert vaccinator himself, and it was his custom, in a doubtful case, to perform a second vaccination a

few days after the first: and he remarked that the second vesicle made "immense strides to overtake the first."

After some time it became apparent that Dr. Jenner's estimate of the protecting power of the vaccine disease had been set too high. He had hoped and believed, as others also had, that the cow-pox would in all cases prove a perfect and permanent protection against the small-pox; but those hopes have been disappointed. Doubtless complete protection is the rule; but — how thoroughly and regularly soever the vaccine malady may have proceeded—it is most certain that very many exceptions to this rule have taken place, and are daily taking place around us.

And this fact, which has long been too glaring to be denied or explained away, has depreciated the value of the process of vaccination in the public esteem, far more than, if rightly considered, it should have done. For it is a remarkable and most important truth that the disease which, in some duly vaccinated persons, follows exposure to the contagion of small-pox, is much milder and shorter even than the inoculated, and *à fortiori* than the natural small-pox. The disorder thus occurring is, therefore, denominated the *varioloïd* disease, or (more conveniently, in my opinion,) the *modified* small-pox, or *post-vaccinal* small-pox.

The constitutional symptoms of this modified disease are, in general, at the outset, and for several days, much the same with those of the regular small-pox. The eruptive fever is of equal length and intensity. There is frequently much headache, and sickness, and sometimes even delirium. The eruption begins about the third day: it is often copious, and sometimes confluent; and in the confluent cases the eruptive fever does not entirely subside so soon as the crop of pimples has come out.

It is in its subsequent progress that the complaint is modified: in respect both to the appearances presented by the skin, and to the constitutional symptoms.

Three distinct kinds of eruption have been observed —

1. The eruption sometimes approaches in its character and course very nearly to that of the ordinary small-pox. The pustules fill up, have the central depression, and ultimately crust over, and the face swells. But this course is performed in a shorter time than that of the ordinary disease, and the pustules are usually smaller. This is the severest and the least common form of the modified small-pox.

2. Sometimes the papulæ show a little fluid on their tops only, but never fairly suppurate, nor break; but the vesicles dry up, and hard prominences remain, with livid bases and horny summits.

3. There are other cases in which a great part of the eruption consists of red pimples, which soon become livid, but contain from first to last no fluid whatever.

In the majority of instances of modified small-pox, all these forms of eruption co-exist. Some of the papulæ go on to suppuration, others become crowned with a horny summit, and others never exhibit any fluid at all.

But the most important characteristic of the modified disease, is the total absence of secondary fever. The constitutional disturbance which, for the first week, may have been as severe as in the ordinary small-pox, generally subsides entirely when the eruption has reached its acme. The patient is convalescent just when, in the unchecked and regular form of the malady, his danger is beginning to be most urgent.

These two circumstances, then — the short duration of the eruption, and especially the absence of secondary fever — furnish the broad distinctions between the regular and the modified small-pox: and almost always, when vaccination has been thoroughly effected, and small-pox occurs afterwards, it occurs in this modified form; and the modified form of small-pox is seldom fatal, though instances of death resulting from it now and then happen.

In relation to this modified or post-vaccinal disease, several questions of the highest practical moment and interest have arisen, which by slow degrees, and under careful and multiplied observation, may now be said to have found their solution.

The first is, whether the protecting influence of cow-pox upon the human frame diminishes by lapse of time, and at length wears out. There is ample evidence to show that, sometimes at least, it does. Certainly in many, but not in all, of those who have gone through the vaccine disease, vaccination repeated at a distant period reproduces, in a greater or less degree, its primary effects. A friend of mine, who was vaccinated in 1799, has a son nine or ten years old, who was vaccinated at the

age of three weeks. Both of them have lately been revaccinated. The boy was somewhat affected by the renewal of the operation; the father not at all.

It may well be doubted whether *all* those who are susceptible of some impression from a second vaccination would become infected with small-pox under ordinary exposure to its contagion. That many of them would so contract the disease, and that all of them would be *endangered* by such exposure, is too certain. And a second question immediately presents itself; namely, whether this repetition of the operation of engrafting the cow-pox renews, or adds to, their security against small-pox. Happily, this question may also be answered in the affirmative; and answered by statistics of the amplest comprehension. In his able and most conclusive digest of the whole subject, published by the General Board of Health, Mr. Simon shows that during the five years, 1833-7, though small-pox infection had been sixteen times imported into different regiments of the army of Wirtemberg, there had ensued among the 14,384 revaccinated soldiers, one single instance only of modified small-pox. Still more satisfactory experience is that of the Prussian army. "In Prussia (as in Wirtemberg) the practice of revaccination grew out of the knowledge that small-pox would attack a certain proportion of those who had been vaccinated only in infancy. During the ten years preceding 1831, cases of post-vaccinal small-pox were increasing in number and fatality, and within the three years 1831-33 there had occurred no fewer than 312 *deaths* by small-pox. For the last twenty years the Prussian army has represented an almost entirely revaccinated population. And what has been the contrast? 104 annual deaths by small-pox was the last experience of the former system; two annual deaths by small-pox has been the average for the revaccinated army. Analyzing moreover the forty fatal cases of small-pox which during the last twenty years have occurred in the Prussian army, we find that only four of the number were of persons who (it is said) had been successfully revaccinated."

Similar facts, equally cogent with these, may be gathered from the experience of other countries. Mr. Marson, the resident surgeon to the Small-pox and Vaccination Hospital, London, states "that not one of the nurses or servants of the hospital has had small-pox, for the last twenty years. They have all been either vaccinated or revaccinated on coming to live at the hospital." The same gentleman holds "that as a matter of safety, it is well for all persons who were vaccinated in infancy to be revaccinated at puberty, this measure being more especially requisite for those who, though vaccinated, have no cicatrix remaining." He recommends also, as a matter of precaution, that all persons should be revaccinated on the appearance of small-pox in the house wherein they are residing.

But, thirdly, is there any ground for supposing that the wished-for protection ever fails to be conferred, because the operation is performed too early? None whatever that I know of. In fact there is unquestionable evidence that, for the full attainment of its defensive purpose, *gratuitous* vaccination at least is, in this country, performed too late. It appears from official tables published under the authority of the Registrar-General, that no less than one-fourth—*i. e.* twenty-five per cent.—of the whole mortality from small-pox in England and Wales happens in infants less than one year old; and as much as eleven per cent. within the age of four months. Within the fifth year the proportion reaches the enormous amount of from seventy-five to eighty per cent. These facts proclaim the necessity of *early* vaccination. It should be as early as is consistent with the safety of the child. Certainly it should never be delayed, except under special circumstances of excuse, beyond the third, or at most the fourth month after birth.

A fourth question is how far the frequent failure, in late years, of complete protection can be ascribed to the circumstance that the vaccine virus has been repeatedly transmitted from one human being to another, and its supply thus kept up, without any fresh recurrence to the cow, the original source of the disorder. Dr. Jenner was, himself, not without apprehension that this might prove a cause of failure. For one year I had a seat, as the Senior Censor of the College of Physicians, at the National Vaccine Board, and I then had opportunities of satisfying myself that lymph which had been transmitted without interruption from person to person ever since the time of Jenner, continued to generate what seemed a very perfect cow-pox vesicle. And it is the expressed opinion of the permanent members of that Board, "that the

vaccine lymph does not lose any of its prophylactic power by a continued transit through successive subjects." Mr. Simon has, however, stated some strong grounds for suspecting that the "occasional impermanence of protection may depend upon impairment in the specific power of vaccine contagion,—an impairment arising in the transmission of that contagion through many generations of men." It was alleged by M. Brisset, in France, as early as 1818, that the past ten years had made a marked difference in the visible characters of the vaccine vesicle: that it had become necessary to establish, instead of Jenner's two vesicles, eight or ten points of infection. Dr. Meyer, of Kreutzburg, states that on examining, in 1824-25, nearly four thousand vaccinated persons of all ages, he found the older scars much better marked than the recent ones; that, according to the testimony of many vaccinators, the proportion of unsuccessful to successful vaccinations was every year increasing; and that the cicatrices resulting from his own use of lymph recently obtained from the cow, were again after the old normal type. Dr. Gregory and Mr. Estlin, in this country, have adduced similar facts in evidence "that the vaccine-lymph, by passing through the bodies of many persons, loses, in process of time, some essential part of its activity."

This suspicion gathers force from a very curious result of the experience furnished by the Prussian army. It appears that where the vaccine supply has seldom or never been renewed from the cow, the proportionate resusceptibility of vaccine disease at a given age (and therefore it may fairly be presumed the susceptibility of small-pox also) has undergone a progressive increase: just as post-vaccinal small-pox has undergone a successive increase. "And (argues Mr. Simon) it is difficult to conceive how the infantine generations of a country could, crop by crop, successively derive less permanent constitutional impressions from vaccination, unless the efficient cause of those impressions—the vaccine contagion itself—had year by year undergone enfeeblement of its powers."

On this point, as well as on others, the statistical experience of the Prussian army is immense. The revaccination of recruits "extends annually to some forty or forty-five thousand operations. It is reported upon annually. Its records run back twenty-four years. Its subjects are of like age, in like proportions, and under like circumstances. When this system of revaccination commenced, in 1833, the proportion of successful results (of those, that is, who again *took* the disorder) was thirty-three in every hundred. Now the annual per-centages of successful results, for the whole time during which revaccination has been practised in that army, runs thus: 33, 39, 42, 46, 49, 50, 51, 54, 57, 58, 57, 57, 58, 60, 64, 64, 64, 61, 64, 69, 69, 69, 69, 70. *The last proportion of success exceeds the double of that with which the series commenced.*" Supposing the first vaccination to have preceded the second by twenty years, "*the vaccinations of 1836—tested by eventual resusceptibility to cow-pox—were not half so stable as the vaccinations of 1813.*"

In the fifth place, there are yet moot points respecting the number of vesicles, and the degree of constitutional disturbance, which are requisite to insure, and to prolong, the protective power of vaccination. The constitutional effect will bear some proportion to the number of vesicles; and of these, it would seem, there should be several; and one or two of them, at least, should be suffered to pursue their entire course untouched. Mr. Marson believes that "vaccination may be relied on, when four or more vesicles have formed which have left good dotted cicatrices." During the five years of 1852-56, of 353 patients admitted with small-pox after vaccination into the Small-pox and Vaccination Hospital, having each four or more vaccine cicatrices, one only died of small-pox.

The same gentleman, who tells us that he has vaccinated between forty and fifty thousand persons, asserts that "one of the principal causes of failure in vaccinating, and of subsequent insecurity of the individual, even when the vaccination does take effect," is the want of care in the selection of the vaccine lymph. "Lymph for use is in its best state on the seventh day of the progress of the vesicle it is taken from—the day week from the vaccination. It should be taken when the vesicles are plump, and just before the formation of the areola. Under no circumstances should it be taken for use later than twenty-four hours after the areola has begun to form." If this rule were invariably observed, there would be, Mr. Marston believes, very few cases of severe small-pox after vaccination. "A serious error in vaccinating is the use of blunt lancets. It is impossible to have a lancet too sharp for vaccinating."

"The lymph should be introduced by a puncture of a valvular shape, from above downwards, so managed that the lymph at each puncture may gravitate into the wound. In this way, the lymph may be introduced in five punctures—the number I recommend—from half to three-fourths of an inch apart, without recharging the lancet: care being taken that the punctures are not bruised." "With good lymph, and the observance of all proper precautions, an expert vaccinator should not fail of success, in his attempts to vaccinate, above once in one hundred and fifty times; yet a large number of those who take upon themselves the duty, think they do very well if they succeed, however imperfectly, five times out of six."

With regard to a sixth question, the most important of all, we may speak very decidedly; and it is a question concerning which it is of the utmost consequence that medical men should form, and disseminate among the public, correct opinions: I allude to the comparative merits and advantages of *inoculation with small-pox*, and *vaccination*.

The advantages of the practice of inoculation to the individual, supposing him doomed to have small-pox, were great and obvious; to the community at large they were very doubtful. It gave the doomed individual, for certain, an ugly disease, which was comparatively free from danger, in exchange for the chances, on the one hand, of contracting a very hazardous form, and on the other, of escaping altogether from any form, of variola. We need not inquire which is the most eligible branch of this alternative; we know which was by most men actually chosen. But the practice of inoculation, by carrying the virus and the disease into every village throughout the length and breadth of the land, filled the country with contagion; insured the disease to all who were subjected to the operation, and diminished to all who were not, the chances of escaping it. No doubt the distemper was produced artificially in many more persons than would have caught it naturally, had inoculation never been thought of. So that while the relative mortality, the per-centage of deaths from small-pox, was lessened by this practice, the absolute mortality was fearfully increased. Such at least is the judgment expressed by most who have thought and written on the subject. Dr. Heberden compared the number of deaths ascribed in the London bills of mortality to small-pox during the first thirty years of the last century, with the number during the same period of years at the close of the century, and he found that they had increased from 7·4 per cent. to 9·5 per cent. To be sure, some allowance must be made for the increase in the whole population of London during that interval; but on the other hand we must take into account the deaths (not noted in those bills) which followed the inoculation of small-pox in secluded villages, where, but for that practice, the poison might seldom have been found. It is right, I say, that this matter should be steadily contemplated, in all its lights, and with all its shadows, in order that the unspeakable blessing conferred upon mankind by the researches of Dr. Jenner may be fairly set forth, and adequately appreciated. The vaccine virus produces a slight disorder, which is attended with no risk, and which (unluckily I may say) is not communicable except by direct engrafting. It not only does not disseminate a dangerous and deadly poison, but if rightly used, it affords the means of eradicating from a well-regulated community, or at least of confining within narrower limits, the most loathsome pestilence which the world has known. Where vaccination is, the contagion of small-pox need never come. In Denmark, as I told you, variola had at one time disappeared before the defensive influence of compelled vaccination. Chance, and a careless security, engendered by the absence of the pest, have led to its reintroduction there. It is much to be regretted that the vaunted liberty of this country has hitherto rendered it almost impossible to enforce by law a practice which would be so conducive to the public weal. Some good might be done by enacting that no person should be eligible to even any parochial office of trust, honour, or profit, who could not produce a certificate that he had been duly vaccinated. Compulsion in some form is clearly defensible and just; and compulsion by *fine* is perhaps the least objectionable form. It is well remarked, in an instructive report on this subject, by a Committee of the *Epidemiological Society*, that "though it may be doubtful how far, in this free country, it is justifiable to compel a person to take care of his own life, or of that of his offspring, it can scarcely be disputed that no one has a right to put in jeopardy the lives of his fellow-subjects. The principle of so using one's own as not to injure

another's, is one which has always been acted upon in our legislation as regards property and personal nuisances; and it is but an extension of the principle to apply it to questions of life and health." Statistical returns have shown that the proportionate mortality from small-pox in England and Wales, is considerably more than double what it is in any of those continental States in which vaccination is more or less stringently enforced.

A so-called *compulsory* Act was indeed passed in 1853; but as no public officer of any kind was appointed whose duty it should be to warn or to proceed against offenders, the Act has become nearly a dead letter.

The benefits which this safeguard, of vaccination, confers on the individual are scarcely inferior to those which it is calculated to bestow upon society. It unfortunately does not give complete protection against small-pox to all, but it gives complete protection to many. And you must recollect that small-pox itself is not a universal and absolute assurance against its own return. But the cow-pox relieves all from the necessity, imposed by inoculation, of coming within the sphere of the variolous contagion. It renders many, I repeat, impregnable to that poison, if they do chance to be within its range; and its advantage to the comparative few who suffer the double misfortune of being exposed to the contagion of small-pox, and of being affected by it, is this, that it gives safety, though not exemption; that it takes away the sting and peril of the variolous disease, by curtailing it of the secondary fever. At the very worst, it leaves the individual liable, by a twofold ill luck, to contract a form of small-pox not more dangerous than that which he would voluntarily accept by submitting to the operation of inoculation.

It is not difficult to adduce authentic evidence in illustration of this reasoning; indeed I have already put before you incidentally much and striking evidence of that kind.

The following tables were compiled by the committee just now mentioned, to show the gradual diminution in the mortality from small-pox in London, as compared with the mortality from all causes, since vaccination has been introduced; notwithstanding its hitherto imperfect employment.

Table showing the average of deaths from small-pox out of every 1000 deaths from all causes within the bills of mortality during the last half of the last century—the half century preceding vaccination.

For the 10 years ending 1760	100
“ “ 1770	108
“ “ 1780	98
“ “ 1790	87
“ “ 1800	88

Table showing the same during the first half of the present century—the half century succeeding the introduction of vaccination.

For the 10 years ending 1810	64
“ “ 1820	42
“ “ 1830	32
“ “ 1840	23
“ “ 1850	16

From the same source I take the following significant statement respecting the prevalence of small-pox as an epidemic in London.

The frequency of epidemics in London has been:—

Before protection as 42;
During inoculation as 54;
During vaccination as 14.

It is shown in Mr. Simon's Blue-book that the fatality of small-pox in Copenhagen is but an eleventh part of what it was before the introduction of vaccination; in Sweden, little over a thirteenth; in Berlin, and in large parts of Austria, but a twentieth; in Westphalia, but a twenty-fifth.

An able paper, to which I am desirous of directing your attention, has been published on this subject, since I previously addressed you, by Dr. Stark, in the 64th volume of the *Edinburgh Medical and Surgical Journal*.

His object is to prove that the increased mortality from small-pox in this country

of late years, is owing more to the *neglect* of vaccination, than to any failure of its protecting power.

He shows from the reports of the Registrar-General, and from other authentic documents, that in London, Manchester, Liverpool, Edinburgh, Glasgow, Perth, and Dundee, more than 80 per cent. of all the deaths from small-pox, happen in children under five years of age.

Now it is in this very class, *if duly vaccinated*, that the mortality ought to be the least; whether we suppose the protecting power of the vaccine virus to be lessened and short lived in consequence of continual transmission through a series of individuals; or whether we suppose it gradually to wear out in each individual subjected to its action.

Dr. Stark adduces also ample statistical evidence that in many of the great European States, a large proportion of the children born, remain unvaccinated.

He brings forward statements which confirm the fact, already mentioned, that small-pox itself is by no means a sure protection against a recurrence of the same disease.

Small-pox after small-pox is supposed to be much less common than small-pox after cow-pox. But in estimating this proportion we must bear in mind the comparative rarity, now-a-days, of primary small-pox. If, indeed, we could trust to the test of revaccination, we might conclude that small-pox is not a more effectual safeguard against small-pox, than the cow-pox is found to be. In the Hanoverian army, in the years 1837, '38 and '39, revaccination produced the true cow-pox vesicle in 11 persons out of every 100, was partially efficient in 27, and failed altogether in 62. A number of the men who had gone through small-pox, were also subjected to the general vaccination, and, curiously enough, its various effects upon them were in precisely the same proportions, as among those who had previously been vaccinated.

So Heim gives the following comparative view of the results of revaccination in the army of Wirtemberg.

Among 100 men who were vaccinated after having had small-pox, the operation succeeded in 32, produced a modified effect in 26, and no effect at all in 42.

And among 100 men who were vaccinated for the second time, the operation succeeded in 34, produced a modified effect in 25, and no effect at all in 41.

But the most striking part of Dr. Stark's paper is that in which he collects and exhibits evidence, which seems perfectly conclusive, of the immunity conferred, for the most part, by vaccination, from the subsequent occurrence of fatal small-pox.

In a general population like our own, all observation on this point is vitiated and made valueless by the uncertainty that exists respecting the ratio of the vaccinated to the unvaccinated portion of the community. It is different in our armies. Every recruit is closely examined: and if he have not previously undergone cow-pox, or small-pox, he is forthwith vaccinated. Mark now some ascertained facts relating to men thus cared for, of nearly the same age, living in the same place, surrounded by similar external circumstances, and subjected to constant and vigilant supervision.

From the Government "*Statistical reports of the sickness, mortality, and invading, among Her Majesty's troops*" for 20 years, viz., from 1817 to 1836 inclusively, we learn that

In Dragoon Regiments and Guards, with an aggregate strength during that period of 44,611 men, and a total mortality of 627, there were but three deaths from small-pox.

Among the troops at Gibraltar, one death only from small-pox occurred, the aggregate strength being 60,269, and the whole mortality 1291.

In the West Indies, although several epidemics of small-pox had ravaged the islands within that period, not one person died of the disease among the British or white troops, with an aggregate strength of 86,661, and a total mortality of 6803: while among the black troops on the same station, with an aggregate strength of 40,934, and a mortality of 1645, there was not even one *case* of small-pox.

"At Bermuda, Nova Scotia, New Brunswick, Cape of Good Hope, and the Mauritius, not a single death from small-pox occurred during those 20 years; and even the white troops of Western Africa wholly escaped this disease, which was carrying off hundreds of the black unprotected population."

In Malta, from 1818 to 1836 inclusively (a period of 19 years), the aggregate strength of the British troops was 40,826, the total mortality 665, and the mortality from small-pox 2. Yet in the years 1830 and 1831, small-pox raged there as an epidemic, and destroyed 1169 persons: for in 1830, there died of small-pox 1048, the total mortality being 3407; and in 1831 there were 121 deaths from small-pox, out of an aggregate mortality of 2583.

Again: in Ceylon three epidemics of small-pox occurred during the 20 years included in the Government reports; namely,

In 1819, when of the natives 7874 took the disease, and 2945 died.

" 1830,	"	"	806	"	"	169	"
" 1834,	"	"	425	"	"	94	"

Yet in the same island, during the very same period, there were among the white troops, with a total mortality of 3000, 4 deaths from small-pox (out of 8 cases); among the Malay troops, with a total mortality of 858, 9 deaths from small-pox; among the pioneer corps, with a total mortality of 647, 1 death from small-pox. And in the last of these epidemics, Dr. Kinnis states that not one instance of the disease appeared among the white or native troops.

Facts equally conclusive are to be found in the statistics of our armies in India. But I need not go into further detail.

Surely we may perceive—in authenticated statements like these—how inadequately the great preventive remedy of small-pox has hitherto been for the most part applied in this country; how successful might become its thorough application. Surely now that the maxim *salus populi suprema lex* is beginning to be acknowledged by our legislators, any general sanitary enactment must be held defective which does not provide for and compel effectual vaccination, and punish variolous inoculation, and shut up in strict quarantine every case of small-pox as soon as its existence in the community is discovered. By these three provisions—and probably by nothing less than these—the seeds of that dire distemper would gradually become scarce and finally disappear; and the soil upon which they might still chance to light would be made unfruitful of the deadly harvest.

There yet remains a highly interesting, but a less practical question. Dr. Jenner, as I stated before, believed that he had traced the cow-pox to its origin in the heels of the horse affected with *the grease*. It has since been made out, that the disease which, in the horse, corresponds with and produces the specific malady of the cow, is a vesicular eruption, having no necessary connexion with the grease, but extending sometimes all over the animal's body. Now the question is, whether these two distempers, occurring in the cow and in the horse, are identical in their essence and nature with the small-pox of man. If so (as Dr. Jenner believed, and Dr. Baron strongly maintained), a part of the mystery attending the whole subject vanishes. The protection furnished by the cow-pox resolves itself into the more familiar law, that certain diseases engendered by animal poisons, happen to the same individual but once, and shield the body against their own recurrence. In conformity with this theory, Dr. Baron named the disorders respectively, variolæ, variolæ vaccinæ, and variolæ equinæ.

The notion, you see, was this, that the vaccine disease is in truth small-pox, rendered mild by passing through the system of the cow. The great object of inoculating the small-pox is to produce a benignant form of that disease, by diminishing the number of pustules. The cow-pox diminishes the number to one; and while it reduces the severity of the disorder to a *minimum*, it absolutely takes away its power of propagating itself, except by a direct engrafting of the visible virus. The disease is not sufficiently intense to taint the air with poisonous effluvia. At the same time it affords (*perhaps* somewhat less surely and less permanently) the customary protection. Such was Jenner's theory, which was intelligible and plausible, and supported by strong facts and persuasive reasoning; for all which I may again refer you to Dr. Baron's book.

This plausible and attractive theory has become demonstrated fact. Researches subsequent to Jenner's have made it "matter of almost familiar experiment" (I state the whole proposition in Mr. Simon's condensed but clear language) "that the infection of small-pox may, by inoculation, be communicated from man to the cow; that

its result is an eruption of vesicles presenting the physical characters of cow-pox; that the lymph from these vesicles, if implanted in the skin of the human subject, produces the ordinary local phenomena of vaccination; that the person so vaccinated diffuses no atmospheric infection; that the lymph generated by him may be transferred, with reproductive powers, to other unprotected persons; and that, on the conclusion of this artificial disorder, neither renewed vaccination, nor inoculation with small-pox, nor the closest contact and cohabitation with small-pox patients, will occasion him to betray any remnant of susceptibility to infection."

To Dr. Gassner, of Günzburg, to Dr. Thiele, of Kasan, to Mr. Ceely, of Aylesbury, and to Mr. Badeock, of Brighton, belong the praise of having worked out, by careful and repeated experiments, this most important truth.

If, as Dr. Heim asserts, there are no less than five kinds of spurious cow-pox, all communicable by inoculation from the teats of the animal to the human body, it follows that, in having recourse, from time to time, to lymph recently obtained from the cow, it should be such lymph only as results from inoculation of the cow with small-pox.

[The following presents a very fair exposition of the views of a large portion of the physicians of the Continent of Europe in relation to the protective powers of vaccination. It is the substance of a report made to the Academy of Sciences of France, on the 25th of February, 1845, by the Committee on Vaccination, to which were referred the various essays sent in by the competitors for the prize proposed by the Academy for the most satisfactory solution of the following questions:—

1. Is the preservative power of vaccination absolute, or merely temporary? If it is temporary only, determine, by accurate experiments and authentic facts, what is the period for which the vaccine matter exerts its protective influence against small-pox?
2. Has vaccine matter, taken directly from the cow, a more certain and durable protective power than vaccine matter transmitted a greater or less number of times through the human subject?
3. If the protective power of vaccine matter becomes enfeebled, should it be renewed; and if so, how?
4. Is it necessary to vaccinate the same individual several times, and if so, after how many years should the vaccination be repeated?

The portion of the report of which the following is an abstract, relates to the first two questions only.

The protecting power of vaccination being definitely established, the question arises—is it possible, after forty-five years' experience, to determine the limits of that power? The answer to this question is extremely difficult, as it embraces inquiries not in France alone, but throughout the whole world: in fact, a general investigation of every case in which vaccination had been formed could alone supply the fundamental elements of the problem to be answered. The competitors for the prize have particularly examined how vaccinated persons are circumstanced during the prevalence of epidemic small-pox; in other words, what is the proportion of vaccinated persons in the entire number of those attacked with small-pox. The protective power of vaccination is, by this mode of investigation, reduced to a numerical question. An attentive examination of what occurred during thirty epidemics of small-pox in France, shows two important facts:—First, that somewhat more than one-third of the entire number of persons attacked with the small-pox had been vaccinated; secondly, that the mortality among the vaccinated persons was very small. According to the author of one of the memoirs, more than one-third of those attacked in the epidemics which occurred at Montbeillard had been vaccinated, but there was no corresponding increase in the amount of mortality amongst the vaccinated patients; and the same result was observed in the epidemic of 1828, at Marseilles. The same results follow, also, from the examination of the epidemics that have occurred in England, Sweden, Denmark, Italy, Malta, Geneva, &c.

The fact, then, being established, that vaccinated persons can become affected with small-pox, and the proportion so attacked during the epidemics being nearly determined, a most important problem remained to be solved—viz., *What was the condition of the vaccinated persons affected as regarded the mere fact of their vaccination?* The authors of all the memoirs agree in stating that vaccinated persons were not affected indiscriminately or by chance, as it were; on the contrary, the small-pox seems to make a kind of selection from amongst them. With some exceptions, the

small-pox attacks those who have been vaccinated since a long period, and spares those who are recently so. An examination of the tables published in various parts of Europe proves positively, that children are seldom attacked with small-pox before the ninth year after vaccination; and also the converse fact, namely, that it attacks in preference persons who had been vaccinated fifteen, twenty, thirty, or even thirty-five years previously. A general fact, which may be anticipated from the history of eruptive complaints is, that after the age of thirty-five years, the aptitude of vaccinated persons to contract small-pox becomes so slight that it may be considered as having vanished.

An investigation of the facts relative to the concurrence of small-pox in vaccinated persons leads to the three following conclusions:—First. The protective power of vaccination is absolute and general for the first five or six years, and even to the eleventh or twelfth year, to judge from the experiments on revaccination. Second. After the foregoing period, a part, but a part only, of those vaccinated again become liable, especially under the influence of an epidemic, to contract small-pox. Third. The greater number of those vaccinated probably remain completely protected from small-pox during their entire life.

Has the cow-pox, taken directly from the cow, a more certain and permanent protective power than vaccine matter that has been transmitted more or less frequently through the human constitution? The experiments contained in several of the memoirs confirm the observations made by the Committee on Vaccination, at Paris. The greater intensity of the new vaccine matter, as compared with that long in use, is a fact definitely established by experience in England, Germany, Italy, and France. But is this greater intensity coupled with a greater preservative power? or, as the report puts the question—Is there any relation between the lesser or greater intensity of the local phenomena and the protective power of the *variolous* matter? The experiments made on this point show that the protective power of vaccine matter is not proportionate to the intensity of the local symptoms, but that vaccination with matter taken from the cow is more certain than with old vaccine matter. *Admitting that the protective power of vaccine matter diminishes with time, should it be renewed, and if so, how?*

As to the means of renewal, the first mode employed was the transmission of the vaccine matter from man to the cow—an experiment frequently performed as a matter of curiosity, but only recently sought to be rendered a means of restoring to the vaccine matter its lost energy. The authors of several of the memoirs maintain that the cow, when thus vaccinated, restores the vaccine matter unaltered, and therefore unregenerated; but the commission of the Academy thinks this conclusion too absolute: in fact, it has been established by the experiments of the author of one of these memoirs, that vaccine matter taken from man is regenerated during its transmission through the cow. The same fact results from thousands of experiments made in Bavaria under the direction of the government. Vaccine matter thus regenerated failed in less than *one case in a hundred*, while the failures of the old vaccine matter were nearly *three per cent*. Would it not be better to transmit the vaccine matter through several cows in succession than through one only? The mode, however, which should be preferred to all others—the only one on which we can entirely rely—is, as recommended by Jenner, to obtain vaccine matter from its original source. Several circumstances seem to show that the cow-pox is perhaps of less frequent occurrence than is commonly supposed, and the commission suggests, that those who happen to meet with it should not content themselves, as has been done hitherto, with transmitting it to man, but transmit it to other cows, and thus regenerate the infection.

Is it necessary to vaccinate the same person several times? and if so, after the lapse of how many years should the revaccination be performed? On this head the report first refers to the fact that the revaccinations, performed for a considerable period after the discovery of vaccination, did not succeed, except in some rare cases, because they were performed too soon after the primary vaccination. But when, at a later period, experience showed that the protective power of vaccination diminished with time, the practice of revaccination was resumed, and then succeeded beyond expectation. In some parts of Germany, especially, revaccination has been practised universally in the army, and even in civil life. Physicians, also, who had had small-

pox, in some instances revaccinated themselves with success, of which Dr. Heim is a remarkable example. He attended on his brother for three weeks, while he laboured under confluent small pox, and three weeks after having gone through this decisive trial, he vaccinated himself, and had pustules almost of the ordinary size. M. Moreau, the celebrated accoucheur, who had small-pox in early life, revaccinated himself three times with success.

A document published by the Government of Wurtemberg, which showed that, of 1677 persons affected with small-pox, between the years 1831 and 1836, 1055 had been vaccinated, contributed greatly to extend the practice of revaccination in Germany, and in the north of Europe. In France, the statistics of epidemic small-pox show that the number of vaccinated persons attacked with small-pox constitute more than a third of the whole number of patients affected. It is impossible, therefore, to doubt the propriety of practising revaccination. It is during epidemic small-pox, especially, that the utility of revaccination becomes obvious. Not only have individuals been thus protected, but the spread of the epidemic has been arrested. In Prussia revaccination has been practised in the army since 1833, and the small-pox has been almost entirely extirpated. In Wurtemberg, but one case of variola occurred in five years, among 14,384 revaccinated soldiers, and three only among 29,684 revaccinated civilians. Epidemic small-pox has not appeared in France since 1830, the period when revaccination was commenced. The authors of the memoir agree that during epidemics it is prudent to revaccinate after about the eighth or ninth year.

The answers given by the competitors for the prize to the questions proposed by the Academy, may be thus summed up:—

1st. The preservative power of vaccination is absolute for the majority, and temporary for a small number; and even in the latter it is absolute until adolescence.

2d. Small-pox rarely attacks those who have been vaccinated in infancy before the age of ten or twelve; from which age, however, until thirty or thirty-five, they are particularly liable to small-pox.

3d. Even in those cases in which it fails to protect the individual from an attack of small-pox, vaccination, nevertheless, so modifies the animal economy, as to render the symptoms of small-pox milder, abridge its duration, and considerably diminish its danger.

4th. Vaccine matter taken directly from the cow causes local symptoms of greater intensity; its effects are also more certain than those of old vaccine matter, but after being transmitted for a few weeks through the human subject, the local intensity disappears.

5th. The preservative power of vaccine matter does not seem to be intimately connected with the intensity of the symptoms of vaccination; nevertheless, it is prudent to regenerate vaccine matter as frequently as possible, to preserve its protective power.

6th. The only mode of regenerating vaccine matter deserving of confidence is to procure it from the cow.

7th. Revaccination is the only known method of distinguishing those vaccinated persons that remain fully protected from those that do not.

8th. The success of revaccination is not a certain proof that the person in whom it succeeds was liable to contract small-pox; it merely establishes a tolerably strong presumption that they were more or less liable to the variolous infection.

9th. In ordinary periods, revaccination should be practised after fourteen years, but sooner, as already remarked, during an epidemic.

See also, on this subject, Condie on Diseases of Children, 4th. Ed. — C.]

To avoid breaking the thread which connects the different parts of the main subject, I have postponed to the last what I have to say respecting the *treatment* of small-pox.

This, for a long time, was conducted upon an erroneous principle, and was eminently disastrous. The older physicians attempted to force out, through the skin, the morbid matter existing in the blood. The eruption they considered to be the natural and only cure: and adopting the vulgar maxim, that "it was better out than in," they did all they could to promote a copious eruption, by a hot regimen, by covering the patient with bed-clothes, by keeping the doors and windows jealously closed, and

excluding every breath of fresh air, and sometimes by administering wine and cordials. The celebrated John of Gaddesden, the author of that curious book the *Rosa Anglica*, improved even upon this. He surrounded the half-suffocated patient with red curtains, red walls, red furniture of all kinds; every thing he saw was to be red; for in that colour there was, John pretended, a peculiar virtue. This John of Gaddesden, by the way, was a very sad knave, and the first Englishman, I believe, who had the luck to be made Court physician. He had one medicine so good as to be fit for the rich only; and he recommended a double dose for the wealthy. “Duplum sit, si pro divite.” He flourished in the fourteenth century.

Sydenham was the first, in this country, to employ the opposite or cool regimen in small-pox; and although his prejudiced contemporaries refused to follow his example and adopt his practice, he confidently predicted its final triumph—“obtinebit demum me vitâ functo.”

But it was subsequently to the introduction of the method of inoculation that the cooling treatment was fairly established by the Suttons — two brothers, one of whom, Robert, lived at Bury St. Edmunds; the other, Daniel, at Ingatestone, in Essex. These men, wiser in their generation than the regular physicians, had the good sense to pursue the same plan of general management which had been so prosperous in the East, whence the practice of engrafting was originally imported. Daniel, in particular, became famous for his successful inoculations: and the great secret of his success seems to have consisted in his making one puncture only; exposing his patients much and often to a cool atmosphere; supplying them freely with refrigerant drinks; and restricting them to a spare diet. Under this course, Cullen, who adopted it from the Suttons, declares that ninety-nine times in the hundred, inoculation imparts a distinct small-pox, and very generally of the mildest form.

Now the same principle applies to the casual disease when we have reason to suspect that it is impending, or have the opportunity of treating it at its commencement. The object is to prevent, if possible, a copious eruption; upon which, as we have seen, the severity and peril of the disorder entirely depend. It has been thought that venæsection, by its antiphlogistic power, and, perhaps, by letting out, with the blood, some portion of the regenerated virus, might lessen the number of the forthcoming pustules. But you cannot ensure this effect by blood-letting: and you must bear in mind that, should the eruption prove confluent, suppuration, to a large amount, is inevitable, and — like that of an extensive burn — will require, in order to go on favourably, a certain degree of constitutional vigour.

You may abate the force of the eruptive fever, and keep down, it is believed, the number of pustules, by saline purgatives, so exhibited as to produce two or three loose stools every day, and by free ventilation of the surface of the body. The skin may even be sponged with tepid water, if the temperature be very high.

When the eruption is all come out, if the pimples on the face are very few and distinct, the danger is over, and there is no more to be done. At this period Cullen dissuades the further use of purgatives, as being sometimes hurtful.

But if the pimples on the face are many, and confluent, the patient will still require a great deal of attention. Our business is to look out for, and to meet, untoward symptoms.

About the eighth or ninth day, wakefulness, and restlessness, and sometimes tremors, are apt to come on; and the proper remedies for this set of symptoms, in small-pox as well as in continued fever, are opiates. In variola, when given in full doses at bedtime, their good effects are often very conspicuous the next day.

If the maturation of the pustules should proceed tardily, if they should not fill up properly nor their contents become purulent, then strong broths may be of use, or even wine. But the effects of these must be carefully watched, and their amount adjusted to the necessities of the case.

When the pustules are livid, and intermixed with petechiæ, and putrid symptoms occur, the disorder generally proves fatal. In such cases it is customary to prescribe bark and acids, in addition to the wine and opiates.

The proper plan of managing the patient during the continuance of the secondary fever, is to keep his bowels moderately open by gentle laxatives, or by enemata; and to give opiates once or twice a day. These are the more necessary on account of the irritation of the skin. The cooling regimen must now be given up; and the strength

must be supported by a nourishing diet. Wine and cordials are indicated if the pulse be feeble; but the swelling of the hands and wrists often makes it difficult to feel the pulse.

Various external applications have been tried, with the view of relieving the intolerable itching; which often induces the patients to scratch and tear their faces, and to insure the formation of scars. Cold cream is used for this purpose; or a solution of common salt, applied luke-warm; or a lotion made by mixing a drachm of the *liquor sodæ chlorinatæ* with half a pint of water; or a liniment composed of equal parts of olive oil and lime-water. This may be smeared, from time to time, over the itching surface, by means of a soft camel's hair brush.

Other methods have been devised, having a more direct aim towards the prevention of that pitting or seaming of the face which is only less dreaded by many patients than the threatened extinction of life itself. Finely-powdered camphor, dusted over the surface, is believed by Mr. George to obviate the disfigurement. Mr. Startin produces a little spot of vesication by touching the apex of each pustule on the exposed surfaces of the body with the *acetum cantharidis*, by the help of a camel's hair pencil. Mr. Higginbottom touches each distinct papula with the solid stick of lunar caustic previously moistened; but when the spots are confluent he washes the whole face, about the third day of the eruption, with a very strong solution of the nitrate of silver, using eight scruples to the ounce of water. A similar practice has been adopted, independently it would seem, by Dr. Alexander Howard of Quebec, except that his solution is somewhat less strong, an ounce of water containing a drachm only of the salt. This application, which is repeated from time to time, is said to be not only effectual for its primary purpose, but to be grateful also to the feelings, and even conducive to the safety of the patient; to allay the heat, itching, and tension of the face and scalp, and to abate the cutaneous inflammation. It is said also to give no pain, and to leave the features perfectly free from pitting; while it has the further recommendation of requiring no great skill or care in its use. Its management may be entrusted to a nurse.

The dyspnœa which sometimes comes on late in the disease, is a very ugly symptom. I know of nothing that can be done for it beyond blistering the throat and chest.

LECTURE LXXXVIII.

Chicken-Pox. Measles. Scarlet Fever.

I MUST not omit a short notice of the disorder called *chicken-pox*; for although a very unimportant complaint, it has given rise to many disputes. Other names which it has borne are *varicella*, *crystalli*, *variolæ pusillæ*.

Connected with the small-pox, and arising from the same contagion, there are several forms of eruptive disease. I mentioned the chief of them in the last lecture, as varieties of *modified* small-pox. Now these mild and irregular forms of variola, both parents and medical men, wishing, I suppose, to believe nothing in disparagement of the protecting power of vaccination, are very apt to consider, and to call, chicken-pox; and this error having been discovered, some persons have rushed to, or rather revived, the opposite opinion—equally erroneous in my judgment—that there is no such substantial disorder as chicken-pox; but that all the eruptions which have passed under that name have really been forms of modified small-pox. Dr. John Thompson of Edinburgh, was one of the stoutest maintainers of this doctrine. No doubt an eruption of short duration, and vesicular through the greater part of its progress, is often caused, especially in persons who have been vaccinated, by the contagion of small-pox; but a similar eruption proceeds also from another distinct contagion, that, namely, of chicken-pox.

The best description of the true chicken-pox that I am acquainted with has been given by Dr. Gregory. The disorder is almost peculiar to infants, and children of tender years. Willan has, however, described one unambiguous example of it, in a gentleman thirty years old : and another genuine instance was seen by Dr. Gregory, at the Small-pox Hospital, in the person of an adult female. The eruption is preceded by little or no premonitory fever, commencing usually on the shoulders, neck, and breast, affecting almost always the scalp, but sparing very much the face—which, in small-pox, never escapes.

The eruption is composed from the very first, of perfectly transparent vesicles, surrounded by a very slight degree of superficial redness. They are usually numerous, but distinct. Dr. Gregory says that when the eruption is very copious, the body has the appearance of having been exposed to a momentary shower of boiling water, each drop of which had occasioned a minute blister. Crops of vesicles appear in succession for two or three days ; and while new ones are forming, the first are beginning to shrivel. The vesicles that remain after the second or third day become slightly opaque, and like pearls. When irritated by friction, they sometimes take on so much inflammation as to be converted into pustules. The scabs are small and gummy, dry quickly, and crumble off, instead of being detached in one mass. In a few instances, shallow cicatrices are left by the vesicles. During the short progress of this eruptive disease there is no constitutional disturbance of any consequence.

It has been ascertained of this genuine chicken-pox, or varicella lymphatica, that it occurs once only to the same person ; that it spreads by contagion ; that, nevertheless, it is not communicable by inoculation — whereas the matter of modified small-pox, when engrafted, produces genuine variola ; that it occurs equally among those who have, and those who have not, been vaccinated ; that its course is not affected by antecedent vaccination ; and that the vaccine vesicle and disease proceed with perfect regularity after the occurrence of chicken-pox. Now this does not happen after small-pox.

It appears, from Möhl's work, *De Varioloidibus et Varicellis*, that from the year 1809 to 1823, chicken-pox was annually observed at Copenhagen without concomitant small-pox ; and that both diseases have since prevailed at intervals epidemically, but always under circumstances which satisfied the physicians of the town that their sources were distinct.

It must, therefore, I think, be admitted, that there is a separate disease, called chicken-pox, which springs from a specific poison ; produces a vesicular eruption ; runs a definite course ; has no tendency, when undisturbed, to suppuration ; occurs but once ; and affords no protection against small-pox, while, on the other hand, small-pox affords no protection against it.

The main point of practical importance is, however, this ; that if we meet with any eruption which is at all equivocal, we should use the same precautionary measures for preventing the extension of the disease as if we were sure that it was modified small-pox. But this salutary rule is often, I say, neglected or infringed, to the danger and detriment of those unprotected persons who happen to be in the vicinity of the sick child.

The treatment required in chicken-pox is abundantly simple ; it is the same, in fact, which has been already recommended for the mildest cases of the discrete small-pox.

Another of these blood diseases is *the measles* : called, also, by nosologists, *rubeola*, and *morbilli*.

Like different human faces, all the complaints belonging to this group have the same set of features, and therefore a mutual resemblance, while the separate lineaments differ so much in their character and relative circumstances, as to give to each disease its distinctive aspect. There are also minor shades of difference between individual cases of the same specific malady.

Measles, accordingly, has its stage of incubation, its introductory fever, its period of eruption, its peculiar kind of eruption, its course by stages. It is communicable from person to person, and it generally occurs but once to the same person. On some of these points I spoke before.

The introductory fever is sometimes severe, and nearer in its type to synocha than to typhus. Like all fevers, it begins with lassitude, and shivering, which are soon

followed by heat of skin, acceleration of the pulse, anorexia, and thirst. But the peculiarity in the fever which precedes the eruption of measles is, that it is very constantly attended with an inflammatory condition of the mucous membranes; especially of those which are proper to the air-passages. The eyes become vascular and watery, the eyelids, heavy, turgid, and red. The membrane which lines the nasal cavities, the fauces, the larynx, trachea, and bronchial tubes, is affected. Hence we have, generally, as symptoms, much sneezing, as well as lacrymation, a copious defluxion from the nostrils, soreness of the throat, and an obvious redness of the fauces, and most commonly a dry, hoarse, peculiar cough. In short, the symptoms which usher in an attack of measles are the symptoms of coryza and catarrh. In some instances there is diarrhœa also, indicating a simultaneous affection of the mucous membrane of the intestines; and not unfrequently vomiting: but the vomiting, as in small-pox, ceases upon the coming out of the eruption.

The regular period for the appearance of the eruption is the fourth day of the disease; seldom earlier, frequently later: sometimes as late as the eighth or tenth day from the commencement of the catarrh. The eruption itself is a rash, consisting, at first, of minute papule, which, as they multiply, coalesce into blotches that have, more or less, a horse-shoe or crescentic shape, and leave the intermediate portions of skin of their natural colour. It is two or three days in coming out, beginning, on the face, neck, and arms, then reaching the trunk of the body, and so travelling down to the lower extremities. In this course it resembles the eruption of small-pox. It fades in the same order, standing out three days at least on the face before it begins to decline; so that its whole duration comprises a space of six or seven days. It becomes browner as it fades. You may feel that it is slightly elevated above the general surface of the skin, especially upon the face, which is somewhat bloated and swollen. The parts which the rash has recently occupied are left covered with a dry, small scurf. The cuticle does not peel off in large flakes, as I shall have to tell you that it oftentimes does in scarlet fever, but a great part of it crumbles away in a fine branny powder. Occasionally, yet very seldom I believe, the rash is intermixed with a few small and short-lived vesicles.

This termination of the papulæ is very unlike what happens in variola: and connected with the eruption there are two other important particulars in which the measles differs essentially from the small-pox. In the first place, the fever does not cease, nor even abate, upon the emergence of the eruption; but sometimes increases in intensity. And in the second place, the disorder is not more severe, nor more dangerous, because the eruption is plentiful, or early. So far from it, indeed, that in some of the worst and most perilous cases the eruption is apt to be partial, and to appear late and irregularly.

The eruption is the *distinguishing* feature of measles, but the catarrhal affection is, in every way, the *most important*. Indeed the rash may, and sometimes does, happen without the fever and the catarrh; and nosologists recognize a variety of the disorder under the title of *rubeola sine catarrho*. But it is observed of this variety, that it confers no protection whatever against the recurrence of the malady: in truth, it is most commonly succeeded in a few days by an attack of measles in its regular and complete form.

I need not stop to repeat what I told you in a former lecture about the other general features of this eruptive complaint. The period of incubation is from ten days to a fortnight. The contagion is active enough, though certainly it is less strong and diffusive than that of small-pox. When once introduced into a family or school, the disease rapidly spreads to those individuals who have not already had it. It is capable, though with much less readiness and certainty than small-pox, of being propagated by inoculation; but as the disorder is not rendered milder by being so introduced into the system, this process has no utility or interest, and is never resorted to. Occasionally rubeola visits the same individual twice; but this is an exception to the general rule. Perhaps, in some reputed instances of its recurrence, the first accession may have been without fever and catarrh, and therefore an ineffectual safeguard for the future. I myself know, however, two large families in which most of the children have suffered a repetition of the genuine unmitigated disease.

The measles resembles the other diseases of the group in this also, that at times it pervades a community as an epidemic; at times occurs here and there only, sporadi-

cally. The general character of the symptoms varies considerably in different epidemics. Morton and Sydenham, and after them Sir William Watson, have described visitations of what they call *putrid* measles. Sir William Watson was physician to the Foundling Hospital, and he witnessed two epidemics of this putrid kind among the children in that institution. He states that the eruption appeared unusually early, so early as the second day of the disease; and that, besides cough and dyspnoea, the complaint was marked by extreme debility, and attended with dysenteric diarrhoea. More seemed to die of the intestinal affection than of the pectoral. He lost, in one of these epidemics, nineteen out of one hundred and eighty-three patients. The malignant character of the disorder was manifested by the frequent occurrence of gangrene, both externally and internally. In this low form of measles, the rash is often irregularly and imperfectly developed, and of a livid colour.

Sydenham found that measles of an unusually bad kind prevailed in London in the years 1670 and 1674; the very same years in which small-pox was also remarkably malignant and fatal. This illustrates what I have stated before; viz., that the putrescent tendencies of these and other febrile disorders depend less upon any peculiar virulence in their *exciting* causes, than upon some change previously effected in the human body by the silent and gradual influence of certain *predisposing* causes.

The diagnosis of measles is seldom difficult. In the outset of the fever you may guess what is coming by the coryza, catarrh, and hoarse cough; especially if the disease be about. On the very first day of the eruption, the small, red, and hitherto separate spots are very like the incipient pimples of small-pox. Do not, therefore, at this period, express too confidently your opinion respecting the nature of the complaint. Parents and nurses might be charitable enough to attribute your mistake to inexperience or ignorance. The progress of the disease will soon remove all doubt. The eruption of small-pox presently exhibits some fluid, while that of measles has none—unless, indeed (what is uncommon), a few milary vesicles mix themselves with it. But these make no advance in twenty-four hours. Ordinarily the isolated pimples visible upon the first day soon augment in number, and collect themselves into semicircular groups; and if any question at all arise, it is whether the disease be measles or scarlet fever. I shall presently describe the latter disorder; and then I will point out the marks of distinction between the two.

The prognosis in measles is governed chiefly by the mildness or the severity of the pectoral symptoms. The most common cause of death, in the fatal cases, is inflammation of some one or more of the textures that compose the lungs. And even when this immediate danger has passed by, the disease too often leaves chronic pulmonary mischief behind it. In scrofulous children, and young persons, it frequently awakens the slumbering germs of consumption. And when that specific effect is not produced, it is apt, in adults, to inflict upon the constitution a blow which is never thoroughly recovered from; the patient becoming, from that time forwards, delicate and valetudinary. The prognosis is always unfavourable when the eruption does not stand out well, is of a livid colour, and accompanied with putrid symptoms, or with a disposition to gangrene.

We augur favourably of the case when the thoracic symptoms are not severe; when the fever moderates upon the coming out of the rash; and when the rash is steadily persistent, and there is no excessive prostration of the strength.

Being contagious, and occurring for the most part but once, measles is principally seen in children, although no period of life is exempt from its attacks. In many children the disorder is so slight as to require little more than judicious domestic attentions. The free application of cold air to the surface, which is so beneficial in small-pox, would in measles be unsafe, on account of the pectoral symptoms. For this reason the patient should be kept in bed; with no more clothes, however, or warmth of the apartment, than he is accustomed to in health. The antiphlogistic regimen must be adopted; and when the bowels are not quite open naturally, gentle laxatives should be given. It may be well, also, to prescribe some diaphoretic medicine; a draught, for example, containing two or three drachms of the *liquor ammoniac acetatis*, with half a drachm of the *spiritus ætheris nitrici*, and an ounce of camphor julep, to be taken three or four times in the twenty-four hours.

The most important part, however, of the treatment relates to the remedies to be

employed for the pulmonary symptoms, which in the outset depend, almost always, upon bronchitis. But the inflammation is apt, in severe cases, to spread insidiously from the mucous to the other tissues — the bronchitis becomes pneumonia — and we find, after death, some portions of the lungs hepatized; usually small portions. For the most part, however, it is extensive inflammation of the bronchial mucous membrane that we have to dread. And really I cannot give you any better or fuller directions with respect to the management of these inflammatory affections, than I endeavoured to lay down when I was speaking of *bronchitis* and *pneumonia*, as they occur idiopathically. You will judge of the extent and severity of the inflammation, partly by the common symptoms, partly by the help of your ear; and you must apportion your remedies to that intensity, so judged of. You will take blood by leeches from the chest, apply a mustard poultice or a blister, and give tartar emetic. And it is of importance that whatever kind or amount of depletion is adopted, should be resorted to *early*.

When the rash is about to decline, a spontaneous diarrhoea often sets in, and appears to have a beneficial effect in abating the febrile symptoms. If this natural curative process should fail to occur, it may be imitated by the exhibition of gentle aperients.

In weakly children blisters are apt to cause troublesome sores; and in some epidemics of measles, the sores thus produced show a disposition to become gangrenous. When any such tendency is noticed, blisters had better be avoided altogether. At other times, the inconvenience to be apprehended from a blister may be prevented by one of two plans; either by interposing a piece of silver paper between the blistering plaster and the skin; or by suffering the blister to remain upon the part three or four hours only, then taking it off, and applying a poultice. The cuticle will rise under the poultice, and the sore will not, in general, be a troublesome one.

If the eruption disappear prematurely, it may sometimes be restored by putting the patient into a warm bath. And if he be at the same time, in a low state, especially if what I have called putrid symptoms threaten or show themselves, you must treat the case upon that indication, just as you would in continued fever; giving wine and animal broths, and watching the effects of these, and apportioning their quantity accordingly.

It is of considerable importance to protect the patient from danger *after* the disease has subsided; by warm clothing, by preventing him from going out of doors too early, or being in any way exposed to cold. Pneumonic inflammation, and dysenteric purging, are frequent consequences of the want of prudence in this respect.

In the year 1846, an epidemic of measles spread itself through the group of small islands between Shetland and Iceland, called the Ferøe Islands. The disease was so serious and general, that the Danish Government thought it necessary to send two physicians from Copenhagen, Dr. Manicus and Dr. Panum, to the relief of the Islanders. You may read a short but interesting report upon this epidemic, by Dr. Panum, in the *Archives Générales de Médecine* for April, 1851. It so well illustrates several of the points on which I have been speaking, that I am tempted to extract some of its statements.

In these islands — which are separated from each other by narrow but dangerous channels, and which are debarred from much intercourse with the world, both by their geographical position, and by their having no external commerce — measles had been totally unknown from the year 1781. The disorder was brought to them in 1846, by a man who left Copenhagen on the 20th of March, arrived at the Island of Thorshavn, apparently well, on the 28th, and sickened on the 1st of April. In October, the disease had again disappeared from the islands. During that interval of about six months, of 7782 inhabitants of the seventeen islands, 6000 underwent the disease.

You will notice here the entire exemption from this contagious complaint for sixty-five years, and its immediate and rapid diffusion upon the introduction of the contagion.

In our own island we see the measles chiefly among children and young persons. There it affected persons of every age. In a village containing one hundred dwellers, eighty were laid up with it at the same time.

All the old people who had had the complaint in the epidemic of 1781, escaped it in 1846.

This shows two things—1st. That subsequent immunity from the disease is the rule. This rule was not broken in a single instance. 2ndly. That the protection afforded by one attack does not wear out as life advances.

Again, of the older persons who had been alive in 1781, and had not been exposed to the contagion (and Dr. Panum could reckon one hundred such persons), all took the disease in 1846; whereas a few youths, though they mixed with the sick, were untouched by it.

From this we learn that the susceptibility of the disorder does not decrease as the age increases; and that the reason why it is so seldom witnessed in adults in this country is the same which I before assigned. The great majority have had it during early life, and are therefore incapable of taking it later.

Dr. Panum found—after careful and extensive observation, conducted under circumstances of unusual freedom from the fallacies and uncertainties which beset such inquiries in larger and more complex communities—that a period of thirteen or fourteen days intervened very regularly between the time of exposure to the contagion, and the time of the eruption of the characteristic rash. Take a single example of this from among many.

One of the smaller islands, called, however, Le Grand Dimon, contained eighteen persons only, who all belonged to the same family. A boat manned by a few of them made a voyage to Tveraa, where the disease was rife, and returned after staying there some hours. Up to the tenth day from that time all these voyagers seemed perfectly well. On the 14th day the eruption appeared upon them all; and fourteen days after that, it showed itself with the same regularity in all the other members of the family.

He noticed that the precursory symptoms were of uncertain duration; sometimes they occupied six or eight days, sometimes from four to six, but generally from two to four days.

The disorder proved very catching at the outset of the eruption and during its whole continuance. Dr. Panum holds it to be doubtful whether it is contagious during the preceding stage of catarrh, or the subsequent stage of desquamation.

Isolation was the only sure defence against the disease. Dr. Panum thinks that 1500 persons escaped it, by establishing regulations equivalent to those of quarantine.

I proceed, in the next place, to the consideration of *scarlet fever*.

This also is a contagious febrile disease, attended almost always, during a part of its course, by a rash, and by *sore throat*. It seldom comes on a second time.

There are some distinct varieties of this disorder, concerning which it is necessary that I should say a few words.

The two striking and important features of the disease are the *affection of the throat* and the *affection of the skin*. They may both be well marked; or only one of them may be well marked: and this circumstance has led nosologists to divide one and the same complaint into two independent maladies; to which Cullen and others have assigned the respective names of *cynanche maligna*, and *scarlatina*. When, in an earlier part of the course, I was treating of the diseases of the throat, I purposely omitted the *cynanche maligna*; because that is only another name for a particular form of scarlet fever. If you look to Cullen's definitions of these complaints, you will see how very much alike they are. They both specify inflammation of the fauces, a cutaneous rash, and fever. But in the definition of *scarlatina*, the rash is dwelt upon and described, and the fever is called *synocha*; while in that of *cynanche maligna*, the ulceration of the throat is more insisted on, and the fever is said to resemble typhus. The truth is, that these two kinds of disorder are both caused by the same contagious poison. The malignant sore throat may be caught from a patient who has mild scarlet fever; and mild scarlet fever may, in like manner, be contracted from one who is suffering under the malignant sore throat. The two forms graduate insensibly, in different cases, towards each other; and it would be impossible, even if it were desirable, to draw any strict line of separation between them. Many would say, and probably with truth, that their difference is this; in the one form the

poison of the disorder is seeking its vent principally by the throat, in the other by the skin.

For convenience, however, of description, and for the better direction of the treatment, authors generally make three *varieties* of scarlatina. *Scarlatina simplex*, in which there is a florid rash, and little or no affection of the throat; *scarlatina anginosa*, in which both the skin and the throat are decidedly implicated; and *scarlatina maligna*, in which the stress of the disease falls upon the throat. The epithet *maligna* marks truly the fearful character of this form of the malady.

To these three varieties, Dr. Copland has added a fourth, which he names *scarlatina latens*. This addition is warranted by the fact (certified now by the testimony of several observers) of the manifestation of certain well-known and remarkable sequelæ of scarlet fever, in persons who had been living with others sick of that disease, but in whom its primary and diagnostic symptoms had not occurred, or had occurred in so slight a degree as to escape notice.

I need scarcely remind you of a sort of mystification which prevails among the public about this complaint, and which many practitioners, for no good reason that I can perceive, seem disposed to encourage. Mistaking the Latin and scientific name of the disorder for a mere *diminutive*, you will hear mammas say, "Oh, my children have not got the *scarlet fever*, but only the *scarlatina*." I always disabuse them of this absurd error, when the opportunity of doing so occurs. It can produce nothing but confusion, and the disregard of requisite precautions.

Like measles, and for the same reasons, scarlet fever, though persons of all ages are susceptible of it, is eminently a disease of children; but it is much more to be dreaded than the measles.

It is somewhat strange that scarlet fever was not recognized, in this country at least, as a distinct disease, till about two centuries ago. In all probability it had long existed, and had been always confounded with measles. Morton speaks of it under the name of *morbilli confluentes*; and Hoffman calls it, by a similar mistake, *rubeola rossalia*. The febris scarlatina described by Sydenham, must have been of a very mild kind; for he does not mention any ulceration of the throat. Dr. Fothergill, in 1748, was the first to describe, as a new and separate disorder, that perilous form of the complaint which Cullen designates *cynanche maligna*; and it was long called the Fothergill sore-throat. The identity of this affection with genuine scarlet fever has been slowly established by subsequent observers. The characteristic differences between scarlet fever and measles were first fully specified by Dr. Withering.

The disease begins, as the exanthemata in general begin, and as continued fevers which I have grouped with them are apt to begin, with shivering; lassitude, and rapidly augmenting debility; headache, frequently severe, sometimes with delirium, occasionally with nausea and vomiting. Then, generally on the second day (and Cullen is wrong when he says it is generally on the fourth), the eruption begins to come out. In some of the worst forms of the disease it may, indeed, be deferred till the fourth day.

Although scarlet fever and measles were so long confounded together, the differences between them are well pronounced, and, when once pointed out, are easily enough recognized.

Rubeola is distinguishable, then, from scarlatina—

1. By the presence, at the outset, of catarrhal symptoms—by the sneezing, the cough, the defluxion from the eyes and nose, which precede the rash. There is, doubtless, in many cases of scarlatina, a running from the eyes and nose, but not till late in the disease; at any rate not prior to the eruption.

2. By the absence of severe inflammation and ulceration of the throat; symptoms which always accompany severe cases, at least, of scarlet fever.

3. By the characters of the eruption itself. The rash in measles is more elevated above the surface than in scarlatina, and of a darker colour. In measles it is said to present somewhat the tint of a raspberry, and in scarlet fever to have that of a boiled lobster. In measles the papulæ are collected into semi-lunar groups, leaving interstices between them of healthy skin. The redness of scarlatina commences in minute points, which speedily become so numerous and crowded, that the surface appears to be universally red. They begin on the face, neck, and breast, and extend to the extremities, pervading at last every part of the skin. The scarlet colour is deeper, in

general, about the groins, and in the flexures of the joints, than elsewhere. Lastly, the rash of measles, in its most regular form, appears on the fourth day of the disease; that of scarlet fever on the second.

On the arms and legs the eruption of scarlatina occasionally differs somewhat from that which is visible on the trunk; is more spotty, more papular, and the papulæ are somewhat prominent, while over the body there is a general punctuated blush.

In some cases of scarlet fever (probably in some epidemics, for I observed the phenomena I am about to mention in four or five cases in succession which were brought into the Middlesex Hospital within the space of a month or six weeks), some parts of the red surface are closely studded with little transparent vesicles, containing a thin colourless liquid, and resembling what I described to you before as *sudamina*. In all the instances in which I have seen them, these minute vesicles have been most thickly set on the thorax, and on the front and sides of the neck. The liquid is soon re-absorbed, and the cuticle under which it had been enclosed shrivels up, turns white, and comes off in a thick white scurf: so that the part from which it separates looks at first sight as if it had been powdered. I have recently seen two cases of this vesicular form of scarlatina in private practice. I show you Rayer's delineation of the vesicles.

The eruption, in the most regular and favourable cases, stands out for three or four days, and then begins to fade and decline, becoming by degrees indistinct, and disappearing altogether, in the majority of instances, before the end of the seventh day. About this time desquamation of the cuticle begins to take place, in smaller scurf or scales from the face and body, in large flakes frequently from the extremities. The scarf-skin of the hands and of the feet sometimes separates almost entire. A glove or a slipper of cuticle comes away at once. You may see such things in most museums.

In that variety of the disorder which we call scarlatina *maligna*, the rash is apt to come out late, and imperfectly, and sometimes not at all; and instead of being bright and florid, to present a bluish or livid tint. Sometimes it suddenly recedes; and then, perhaps, appears again: and occasionally it is diversified by purple spots.

Willan and Bateman have given the name of *roseola* to an eruption which is also attended with inflammation of the throat, and between which and scarlatina it is certainly difficult, if not impossible, at first to discriminate. The roseola, however, is not contagious, and has more of a chronic character than scarlatina. It comes and goes, and has no settled or definite course. Dr. A. T. Thomson lays down *this* distinction between them; but I do not know that we can trust to it:—"In scarlatina (he says) the rash first attacks the face, and then extends to the trunk of the body, passing off by the extremities; whereas in roseola the extremities are *first* affected."

The appearances of the *tongue* in scarlet fever are also peculiar and characteristic. In the scarlatina *simplex*, and *anginosa*, it is often covered, at the outset, with a thick, white, cream-like fur, through which are seen projecting the red and exaggerated papillæ; the edges of the tongue being likewise of a bright red colour. The red points gradually multiply, and the white fur clears away, and at length the whole surface of the tongue becomes preternaturally red, and clean, and raw-looking: and after becoming thus clean, as well as red and rough, and like a strawberry, it will sometimes, when the disease goes on unpromisingly, get dry, and hard, and brown—as you know it is apt to be in certain species and stages of continued fever.

The first thing of which the feverish patient usually complains is sore throat, with some stiffness of the neck: and if you inspect the fauces, you will see, without in general so much swelling of the tonsils as occurs in common quinsy, a diffused redness, sometimes of a dark claret colour, including a large part of the palate. In a short time you may perceive that the tonsils and velum are covered irregularly with whitish exudations, or gray aphthous crusts: or, perhaps, you see a sloughy kind of ulceration left by the separation of these crusts.

The progress of the distemper, and its degree of severity and of danger, differ very greatly in different cases. Sometimes the deviation from the feelings and condition of health is so very slight as scarcely to deserve the name of a disease; sometimes the disorder defies all treatment, and the deadliest forms of plague are not more fatal.

In these malignant and terrible cases, the eruption, if it appear at all, is livid and partial, and fades early, and is attended with a feeble pulse, a cold skin, and extreme prostration of strength. Sometimes the patient sinks at once, and irretrievably, under

the virulence of the poison, and life is extinguished in a few hours. A gentleman called one day at my house, and not finding me there, followed me between twelve and one o'clock to the hospital. He wished me to visit his wife, four or five miles out of town, who had been taken ill that morning. He feared that she was about to have scarlet fever, but he was not much alarmed for her safety; for when he found that I could not be at his house before six, he said that that hour would not suit the general practitioner in attendance upon her, and he begged me to fix some time for seeing her *the next day*. I did so; but the same afternoon rapid sinking came on, and the patient was dead very soon after the hour at which I had first proposed to visit her.

In other cases of *scarlatina maligna*, the typhus-like symptoms rapidly deepen; and death, in children, is apt to occur on the fifth day of the complaint; and not uncommonly as soon as the third. The pulse becomes frequent and feeble; the tongue dry, brown, and tremulous; the debility extreme; the breath offensive; the throat is livid, swollen, ulcerated, and gangrenous; and the respiration is impeded by viscid mucus which collects about the fauces. Over this variety of the disease, medicine has comparatively little control.

The chance of recovery is much greater in the *scarlatina anginosa*, when the eruption is florid, and stands well out. But even in this form of the disorder there are many sources of danger, and various ways in which it may prove fatal.

In the first place many of the patients die, apparently from inflammation or effusion within the head. They have violent headache, with furious delirium, which is followed by coma and death.

And, secondly, the state of the throat is full of peril. As the disease proceeds, although the rash may be steadily persistent, the throat becomes foul and sloughy; an aerid discharge from the nostrils, which are so stuffed and swollen internally that the patient can scarcely breathe through them, runs over and frets the upper lip; the parotid and submaxillary glands swell, sometimes enormously; and fever is lighted up afresh. In this way many cases prove fatal in the second week of the disorder. The cervical swellings cause constriction of the fauces and stiffness of the neck; and sometimes, doubtless by interfering with the free return of the blood from the head through the jugular veins, they produce a tendency to coma. With these symptoms there is often also purging, and an excoeriated anus.

The aerid matters furnished by the ulcerating and gangrenous throat irritate the nasal membrane in the one direction, and that of the alimentary canal in the other. We thus account for the running from the nose, the soreness of the *alæ nasi* and upper lip, and the smarting diarrhœa: and the swelling of the parotids and neighbouring glands is evidently caused by absorption of the irritating and poisonous matter from the ulcerated throat. There is just the same relation and dependency between these different local alterations, as between the enlarged mesenteric glands, and ulceration of the follicles of Peyer in typhoid fever; between a bubo in the groin, and a chancre on the glans penis. It is the condition of the throat that gives rise, in these cases, to the most formidable symptoms. The system is reinoculated from that source. Whenever I see the glands much enlarged at the angle of the jaw, and beneath the jaw, in a child labouring under scarlet fever, I augur ill of the case. Sometimes the mischief extends into the larynx, and so destroys the patient. But this is probably a very rare event. There is, however, still another, and a very common consequence of the throat affection—I mean inflammation of the eustachian tube, reaching sometimes the tympanum itself, and causing permanent deafness, either by closing up the tube, or by the destruction of the *membrana tympani*, and of the little bones belonging to it. In one case, which was under my own care, I observed that, for a short time before death, every time the child swallowed, a part of the fluid food ran out immediately at one of its ears. I had no opportunity of examining the state of the part after death, but the disorganization arising from the sloughing ulceration of the throat must have been frightful.

Scarlet fever sometimes befalls parturient women; and then it almost always proves fatal. I have seen three instances only of recovery from this perilous complication.

Scarlatina simplex is scarcely, I repeat, a disease. Sydenham has said of it that it is "fatal only through the officiousness of the Doctor."

Even when the patient has escaped from the complaint itself, he is often exposed

to great hazard and distress from its *consequences*. Children who have suffered a severe attack of scarlet fever are liable to fall into a state of permanent bad health, and to become a prey to some of the many chronic forms of scrofula: boils, strumous ulcers, diseases of the scalp, sores behind the ears, scrofulous swellings of the cervical glands and of the upper lip, chronic inflammation of the eyes and eyelids. The same afflicting results are very common after small-pox also, and measles.

I have several times, when the rash of scarlet fever was disappearing, known pain and swelling of the larger joints to supervene, simulating very closely the local phenomena of subacute rheumatism; and I have noticed that the painful joints were eased and benefited by friction; a circumstance which may help to distinguish this articular affection from true rheumatism. Another distinctive circumstance seemed to be that, although all these patients were children, the heart in no instance became implicated, in connexion with the tumid joints. Upon this point, however, my own experience may have been fallacious. Dr. Scott Alison has recently invited attention to the subject, in an interesting Essay "On Pericarditis, a complication and sequela of Scarlatina." Accepting his facts, I should ascribe the articular affection, and the cardiac affection, whether they occurred together or separately, to one and the same cause; namely to the retention in the blood of a poisonous excrement, by the default of the principal emunctories, and especially of the kidney.

But certainly the most common, and a very serious sequel of scarlatina, is *anasarca*, serous infiltration of the subcutaneous areolar tissue, accompanied often with dropsy of the larger serous cavities. So common is this that Cullen has even introduced the circumstance as a part of his definition of scarlet fever. He found the dropsy a very manageable complaint; but it really is, in many — nay, in most cases, if we look to its possible ultimate consequences — a most formidable one. This affection belongs to the class of *febrile dropsies*. It appears to have no relation, or, if any, an inverse relation, to the violence and danger of the preceding exanthem. It is much more common after a mild, than after a severe disease. This I believe to be chiefly owing to the circumstance that less care and caution are observed in the milder cases during the dangerous period of desquamation and convalescence; a period more dangerous, in that variety of scarlatina, than in any other. In the graver cases the convalescence is slower, and more doubtful; and accidental or careless exposure to cold is more guarded against, or takes place later: whereas, in the slighter kinds of the disorder, the patients are apt to go out while the new cuticle is still forming. The escape of the fever-poison through the large outlet afforded by the skin is checked or prevented. More of it is hurried through the narrower wicket of the kidneys, and gives rise, in its tumultuous and embarrassed outbreak, to what Dr. George Johnson has called "acute desquamative nephritis." If you carefully trace the histories of dropsy succeeding to scarlet fever, you will very frequently find that the fever had been trifling; and that the patient, considering himself well or nearly so, had heedlessly encountered a cold or damp atmosphere so soon as he felt himself strong enough to leave the sick chamber. Plenciz, who has written well on this subject, and who was quite aware of its importance, remarks that those patients who have had much desquamation of the cuticle are the most liable to the dropsy; that it is more frequent in winter than in summer; and in such as are early exposed to the open air after having passed through the fever, than in those who remain longer at home. When the desquamation is over, and the new surface has become in some degree hardened, the peril is past. According to the observations of Dr. Wells, the dropsical symptoms commonly show themselves on the twenty-second or twenty-third day after the commencement of the preceding fever. They have been known to begin as early as the sixteenth, and as late as the twenty-fifth day. When no dropsy took place before the end of the fourth week, Dr. Wells always ventured to state that it was no longer to be dreaded.¹

This anasarca is seldom observed except in children and young persons. The age of the oldest patient that Dr. Wells had known to be so affected was seventeen. Of ten instances of the disease seen by Dr. Blackall, six occurred in children not exceed-

¹ Dr. Tripe, in a paper contained in the *Medico-Chirurgical Review*, for July, 1854, assigns larger limits to the first appearance of the dropsical symptoms, and states that the fourteenth day of the disease is most frequently of all the day of their invasion.

ing the age of ten, and two others in persons who were respectively ten and sixteen years old.

We cannot infer, from this, that the susceptibility of this dropsical condition lessens as years increase. The great prevalence of this variety of dropsy in early life has no direct relation to age as a predisposing cause. The fact is explained by the accidental peculiarities of the antecedent disease. The contagion of scarlet fever is active and widely diffused. Few children escape its agency. Few are capable of taking the disorder a second time. It follows that scarlet fever is rare in adult life: and as dropsy succeeds that disease in a very limited number of instances only, dropsy arising in connexion with scarlet fever must, at the adult age, be still more uncommon.

Yet it is not unknown. One of Dr. Blackall's ten patients was thirty, another forty-two years old. Both of these were women.

In this, as in other species of febrile dropsy, the urine is very dark, olive-coloured, albuminous, and sometimes bloody; and it contains fibrinous casts of the renal tubules, with epithelial cells intermixed.

Not only may one case of scarlet fever differ widely from another case, but very great differences are also observable in the general character of different epidemics. This is true indeed of all the exanthemata. In some epidemics the disease is almost uniformly mild, in some it is fearfully severe and dangerous. The inflammatory symptoms may in one epidemic run high, while throughout another the low or typhous type may predominate. We should learn from such differences not to dogmatize, in reliance upon our own experience of one or two epidemics, respecting the most fitting management of the disorder; nor to criticise ungenerously and with ignorant arrogance the treatment recommended by others, who may have observed the disease elsewhere, or at some former time. These diversities are well illustrated in the histories given of scarlet fever, as it has prevailed epidemically in the charitable institutions for children which abound in and near Edinburgh. In such places the means of studying epidemic contagious disorders are singularly precious and instructive. The inmates are of nearly the same age, are all living under precisely similar circumstances as to food, clothing, shelter, and general habits, and are at the complete disposal, and under the frequent and close observation, of the attending physician. You may read in the *Edinburgh Monthly Journal of Medicine* some very interesting and valuable records of these visitations of scarlet fever from the pens of Dr. Gillespie, Dr. Newbigging, Dr. Andrew Wood, and Mr. Benjamin Bell. Much attention was paid by these gentlemen to the relations subsisting between scarlet fever, the presence of albumen in the urine, and the occurrence of dropsy. This subject has also been carefully investigated by Dr. Warburton Begbie, who had likewise large opportunities of witnessing the disorder in the Edinburgh Infirmary and elsewhere. I have much trust in his conclusions, which are briefly these:—

In most, if not in all cases of scarlet fever, the urine, at one period or another of the disease, contains more or less albumen. With a few exceptions, the time when it begins to appear is shortly after the commencement of desquamation of the cuticle. The albuminous condition is most often transient, and is by no means necessarily attended with anasarca. It lasts from a day or two to ten days, its average duration being four or five days. It may easily be overlooked if the urine be not very frequently examined. The amount of albumen is generally small. When once it disappears from the urine, it never reappears. The specific gravity of the urine remains high, and its quantity is usually plentiful. Here however comes in the connexion with dropsy. If the urine, thus albuminous, become scanty, then the supervention of anasarca may be looked for. While there is no anasarca, the urine may be albuminous, but it contains no casts. As soon as anasarca occurs, casts and epithelium, and sometimes even blood, are found associated with the albumen.

The majority of these cases of scarlatinal dropsy end in complete recovery. No permanent damage is sustained by the kidneys. Yet the instances are not few in which the chronic form of renal dropsy, manifesting itself at some distance of time, has been distinctly traced back to its source in the acute anasarca immediately consequent upon scarlet fever. There can be no doubt that one form at least of the organic renal degeneration described by Dr. Bright does not unfrequently date its origin from an attack of febrile anasarca: and in proportion as facts, accurately

observed, accumulate on this subject, the chain of connexion becomes more clearly visible between acute febrile dropsy, dropsy succeeding scarlet fever, and chronic renal dropsy. It is evident, indeed, that the first two of these three are, in their characters and exciting causes, nearly identical, the only difference between them consisting in the remarkable predisposition towards the second, impressed upon the body, through contamination of the blood, by the preceding exanthem. Both of them again are, in many instances, initiative of the third.

It is natural therefore to expect that, in the variety of febrile dropsy now under consideration, as well as in those which I formerly described, *inflammation*, and especially inflammation of the serous membranes, should be met with, and be evidenced by its unequivocal effects. And it is so. But the dropsy, I am persuaded, has no essential connexion with common inflammation of any part, unless the state of the kidney be of that kind. I have examined the body very carefully in fatal cases, and found the serous cavities full of clear liquid, without a trace of redness or of any of the unmistakable products, or events, of inflammatory action.

The earliest threatenings of this formidable complaint demand attention. Its approach may often, I say, be detected, prior to any more obvious symptoms, by daily examination of the quality and the quantity of the urine. It is usually preceded for a day or two, or longer, by languor and peevishness; frequently by nausea and vomiting, and a costive state of the bowels. The pulse, in the outset, has been found slow, and beating with irregular intervals; but it afterwards grows frequent. The face becomes white and chuffy. Sometimes, as the disease proceeds, violent headache, drowsiness, dilatation of the pupils, convulsions, or palsy, denote effusion within the head. These symptoms may result however from the poisoned state of the blood. Much more frequently the pleuræ are the seat of the internal dropsical accumulation, and dyspnoea is a prominent symptom. Ascites, to any considerable amount, is rare.

The contagion of scarlet fever is active, but uncertain. It is not so strong, nor so uniform in its operation, as that of small-pox; but it seems to be peculiarly subtle and tenacious. Dr. Webster is of opinion that the risk of infection is diminished by frequent spongings of the patient's body with tepid vinegar and water. Fomites infected with the variolous poison soon lose their power to excite small-pox if they are freely exposed to fresh air. But the contagion of scarlet fever lurks about an apartment, or clings to furniture and clothes, for a very long time, even after some care has been taken to purify them. Of this I have known several remarkable examples. I will give you one. The disorder had attacked several persons in a large household. When it was fairly over, the house was left empty, and then (as was supposed) most thoroughly ventilated and purified. A year afterwards the family returned to the house. A drawer in one of the bed-rooms resisted for some time the attempts to pull it open. It was found that a strip of flannel had got between the drawer and its frame, and had made the drawer stick. This piece of flannel the house-maid put playfully round her neck. An old nurse who was present, recognising it as having been used for an application to the throat of one of the former subjects of scarlet fever, snatched it from her, and instantly burned it in the fire. The girl however soon sickened, and the disease ran a second time through the household, affecting those who had not had it on the first occasion. You will be asked at what period the danger of imparting the disease on the one hand, or of catching it on the other, is over; and I would recommend you to answer that you do not know. I am sure I do not: and therefore I always decline the responsibility of giving an oracular opinion on the matter.

I may arrange what I have to say of the *treatment* of scarlet fever, according to the three varieties of it already mentioned, the *scarlatina simplex* — *anginosa* — and *maligna*. Of the *scarlatina latens*, the sequelæ alone become the subjects of treatment.

The first of these requires nothing more than confinement to the house; and the observance of the antiphlogistic regimen in regard to diet; and regulation of the bowels.

With respect to the management of the severer forms of scarlet fever, great differences of opinion have prevailed. I should recommend you to look into Dr. R. Williams's book on *Morbid Poisons*, for some interesting and satisfactory information on

this head. Satisfactory to me at least it is, because the result of it goes to justify that kind of practice which I have always considered to be the safest and the best in this disorder.

In the scarlatina anginosa, the treatment I employ is very much the same as that which I consider proper for many cases of continued fever. If the heat of the surface be very great and distressing, I certainly should not recommend the cold *affusion*, but cold or tepid *sponging* will be very refreshing and beneficial. If delirium should come on, I would shave the scalp, and apply cold to it, and if the pulse were hard and strong, I would take away some blood by leeches: but I would apply the leeches behind the ears rather than to the *temples*. The tonsils, in this form of the disorder, are more swelled and inflamed, and probably a part of the head affection may arise from the disturbance of the balance of the cerebral circulation, produced by the tumefaction around the great veins that return the blood from the head. By leeching the mastoid processes you relieve, I think, both head and throat. If the fever were extreme and the delirium violent, I might take blood cautiously from the arm, while the patient was sitting up, and carefully note the result.

When none of these untoward head symptoms declare themselves, all that we have to do is to keep the bowels open by moderate laxatives. The patient may take saline draughts, which are grateful and cooling. The citrate of ammonia thus administered is what I frequently prescribe: and if the pulse be without hardness, and feeble, I order an excess of the carbonate of ammonia, so that four or five grains of it in each dose may remain unsaturated by the lemon-juice.

With respect, then, to this form of the complaint, the principles of treatment are, not to interfere unnecessarily; to take blood when certain symptoms require it, but to take no more than seems likely to be sufficient for the purpose in view; to bear in mind that the system is labouring under a morbid poison, which we cannot eliminate from the blood, but the dangerous effects of which we are to watch and obviate.

In that worst form of scarlet fever, the scarlatina maligna, all our care will too often be in vain. There appear to me two main sources of danger. The one arises from the primary impression of the contagious poison upon the body, and particularly upon the nervous system, which is overwhelmed by its influence. The patients sink often at a very early period, with but little affection either of the throat, or of the skin. If we can save such patients at all, it must be by the liberal administration of wine and bark, to sustain the flagging powers until the deadly agency of the poison has in some measure passed away. But another source of danger arises from the gangrenous ulceration which is apt to ensue in the fauces, when the patient is not killed by the first violence of the contagion. The system is *re-inoculated*, I believe, with the poisonous secretion from the throat. Now under these circumstances also, quina, or wine, and upon the whole I should give the preference to wine, are to be diligently, though watchfully given. And something may be done, by way of gargles, to correct the state of the throat, and to prevent the distressing and perilous consequences which would otherwise be likely to flow from it. A weak solution of the chloride of soda may be employed for this purpose; or, what I believe to be better still, a solution of the nitrate of silver. If the disease occur in a child that is not able to gargle, this solution may be injected into the nostrils, and against the fauces, by means of a syringe or elastic bottle: or a little mop, charged with the same solution, may generally be used without much difficulty. The effect of this application is sometimes most encouraging. A quantity of offensive sloughy matter is brought away; the acrid discharge is rendered harmless; the running from the nose, and the diarrhoea, cease; and the disease is converted into a form which approximates to the scarlatina anginosa. This is a great improvement upon the old plan of ordering capsicum gargles.

Of late I have been in the habit of directing a solution of the chlorate of potass in water (a drachm to a pint), as a *drink* for patients in scarlatina, as well as in typhus fever. This practice was suggested to me by Dr. Hunt, who tells me he has long employed it with advantage. Under the use of a pint, or pint and half, of this solution daily, I have remarked, in many instances, a speedy improvement of the tongue, which, from being furred, or brown and dry, has become cleaner, and moist.

From several distinct and highly respectable sources, *chlorine* itself has been strongly pressed upon my notice, as a most valuable remedy in the severest forms of

scarlet fever. My informants have stated, that whereas they formerly dreaded to be summoned to cases of that disease, they now, having had experience of the virtues of chlorine, felt no misgivings in undertaking its treatment. Since these representations were made to me, I have not had opportunities enough of trying this drug to enable me to speak confidently of its sanative power: but I shall certainly employ it in future. I presume that its disinfecting properties may, in part, account for the good it does. It probably deprives the foul secretions of their noxious quality.

In the fourth volume of the *Medical Gazette*, Messrs. Taynton and Williams, of Bromley, write in high praise of this remedy, and give a formula for its preparation.

You may make it, for extemporaneous use, in this way.

Put eight grains of the chlorate of potass into a pint bottle, and pour upon them one drachm of strong hydrochloric acid. Keep the mouth of the bottle closed until the violent action has ceased; then add an ounce of water, and shake the mixture well; then add another ounce of water, and again agitate well; and so on until the bottle is full. The chlorate should be pulverized; and in cold weather the bottle should first be warmed.

A table spoonful, or two, of this mixture, according to the age of the patient, may be given for a dose, frequently. An adult may take the whole pint in the day.

We must remember, in this, as well as in the other forms of the complaint, to pay attention to the state of the bowels, and by no means to allow them to remain costive.

I have seldom used blisters in this disease; but an experienced physician has told me that, when applied *early* to the neck and throat, they seem to render the affection of the fauces mild.

When the patient is at length convalescent, he will require careful watching till that period has gone by at which the dropsical symptoms are apt to appear. Very often it is by neglect or imprudence that these symptoms are brought on. The patient should be kept long in bed, and sedulously protected afterwards from all exposure to cold, wet, or fatigue; indeed he ought not to be permitted to go out of the house until the process of desquamation is fairly over; and I would not willingly let a patient go out till some little time *after* this. When dropsical symptoms *do* occur, if they be very slight, they may be removed in general by purgatives, and by digitalis. These patients are always pallid and exsanguine; for this reason, and still more because that remedy has been found actually serviceable in such cases, I would advise a combination of the muriated tincture of iron with the tincture of foxglove. Diaphoretic remedies, too, are beneficial; and in aid of them, or rather as one of the most efficient of them, the warm bath, which may be repeated every night. And inasmuch as we know that the kidneys are at least congested in all these cases, I would always take a small quantity of blood from their neighbourhood, by leeching or cupping the loins. Upon the same ground I should refrain from prescribing stimulating diuretics.

But if there be any indication of *inflammatory* disease of any other internal part, we must adopt more active measures. We have not, *now*, so much to contend with the depressing influence of the original poison, as to dread the consequences of acute inflammation; or of the sudden effusion of fluid, the mere presence and pressure of which may fatally oppress vital organs. We should have for our object to arrest the inflammation—or to promote the removal of the effused fluid—by blood-letting, and by the exhibition of purgative medicines, and of *mercury*. The worst case of this kind that I ever witnessed occurred in a boy of fifteen, the son of a tradesman in my neighbourhood. He had had scarlet fever, *mildly*, and had got well, or nearly well, of it, as he believed; and he went, one evening, into his father's stable, and staid there some time in the cold, during the period of desquamation. A day or two afterwards he began to have headache, and in a few hours more was seized with convulsions of one side of the body, coma, and at length hemiplegia; and his face and extremities became at the same time anasarcous. A considerable quantity of blood was taken from his arm, he was cupped on the temples, and took mercury, till in a short space of time he was profusely salivated. Under this treatment the coma and dropsy rapidly disappeared, and he presently recovered the use of his palsied limbs, and got quite well. I conclude that some effusion took place within the cranium, as well as into the subcutaneous areolar tissue. The plan of treatment followed in this case, modified according to particular circumstances, is that which I should

again pursue, and therefore is what I should recommend you to pursue, in similar emergencies.

You are probably aware that *belladonna* is believed by many to exert a preventive and protecting influence upon the body against the contagion of scarlet fever. Hahnemann, the author of the Homœopathic hypothesis (and thereby of much mischief to mankind), was the first to assert this. The notion was evidently suggested by that hypothesis; for *belladonna*, administered in small doses, sometimes produces a scarlet efflorescence on the skin, and certainly tends to cause dryness and redness of the fauces. This is but a poor foundation on which to rest its prophylactic power. To test that alleged power is not very easy. Other precautions are commonly employed at the same time; there are great natural differences in different individuals with respect to the susceptibility of the contagion of scarlet fever; the prepared extracts of *belladonna* are not seldom worthless and inert. The conservative property, however, of that vegetable has, in my opinion, been completely disproved by the trial of it made in George Watson's Hospital, in 1851, by Mr. Benjamin Bell. Scarlet fever having appeared within the building, *belladonna* was given to fifty-four healthy boys; at first in doses which caused dilatation of their pupils, and impaired vision. The drug therefore was not inert. After this plan had been in operation for a month — after full time allowed, therefore, for the development of the protecting influence of the *belladonna*, if it really possessed any — twenty-three of these fifty-four boys took the disease.

It is sometimes prescribed, by men who have little or no faith in its preventive virtues, in order to give confidence to those employed in nursing the sick, and comfort to anxious parents. But in proportion to the confidence thus produced will be the risk of the neglect of other and better safeguards. For my own part, totally discrediting the defensive power ascribed to the drug, abominating all shams, and believing that so poisonous a substance can scarcely be taken for some time together, even in small doses, without prejudice to the general health — I not only never propose it, but I think myself bound to state plainly my opinion of it, whenever its use is proposed to me.

[The question in relation to the prophylactic properties of the *belladonna* in this disease is a highly interesting one. The severe and fatal character of scarlet fever, particularly when it occurs as an epidemic, renders every means of prevention that can be depended upon with any degree of certainty, of vast importance. In proof of the power of the *belladonna* to guard those who have been placed under its influence from an attack of scarlatina, we have certainly some very strong and respectable testimony. In a paper published by Bayle, in 1830, it is stated that of 2027 individuals to whom the *belladonna* was administered, 1948 were preserved from scarlet fever, and 79 were attacked. Dusterberg reports, that all who were placed under the influence of the *belladonna* for the space of two weeks, were preserved from the scarlet fever. In order to ascertain the real value of the article, he purposely omitted to administer it to one child in each family, and this one alone, according to his report, was seized with the disease. He adds, however, that occasionally a child who had only been taking the remedy during three or four days, was attacked, but the fever was in such cases always mild, and often only manifested its presence by the occurrence of desquamation. Zeuch, physician to the Miliary Hospital for Children, in Tyrol, after 84 of the children were attacked with scarlet fever, was induced to try the prophylactic powers of *belladonna* on the remaining 61 children: with a single exception, all of these were preserved from the fever, although it prevailed all around them. Schenk, Berndt, Köhler, Meglin, De Lens, Massius, Bayle, Godelle of Soissons, and many other respectable practitioners, speak in equally high terms of the preservative properties of the *belladonna*. We have ourselves given the *belladonna* to a number of children, on several occasions when the scarlet fever was prevailing epidemically, with a view of testing its prophylactic powers; but although redness and dryness of the throat, and a diffuse scarlet efflorescence were produced by it, yet in the majority of cases, we never found it in any instance to exhibit the slightest influence in shielding those who took it from an attack of the disease, or in mitigating in any degree its severity. In one case, the efflorescence produced by the *belladonna* was kept up for forty-eight hours; in a week afterwards the child was attacked by the fever in its

most violent form, and died on the fourth day. Recently, however, Dr. Stievenart, of Valenciennes, has published the results of a very extensive trial of the belladonna, as a prophylactic during the prevalence of epidemic scarlatina: which results, if they are correctly stated, and all sources of error have been carefully guarded against in the performance of the experiments upon which they are founded, go very far to prove that the belladonna does actually possess the property of shielding the constitution from an attack of scarlet fever. An epidemic of the disease ravaged, during the winter of 1840-1, several villages in the neighborhood of Valenciennes, when Dr. Stievenart was induced to try the prophylactic properties of belladonna. The fatality of the epidemic was such that 30 had already died out of 96 attacked; consequently any means of prevention was a subject of vast importance. In a small village, out of 250 individuals, 200 took the belladonna, and were all preserved from the attack of scarlet fever. Of the fifty others, 14 were seized with the fever, and four of them died. At the village of Curgies, Dr. Stievenart administered the belladonna to the children at the public school, and allowed them to continue at their lessons, and have free communication with the other children of the village. All to whom the belladonna was administered escaped the scarlet fever, while a few who refused to take it were seized with the disease.

The belladonna was administered in two forms—in solution, or as a powder. Two grains of the recent alcoholic extract of belladonna were dissolved in an ounce of any aromatic infusion, and of this two drops were given to a child of one year old, daily, for nine or ten days: an additional drop being given for every additional year of age. The largest daily dose was, however, limited to twelve drops. When the belladonna was used in the form of powder, half a grain of the powdered root was mixed with a small quantity of sugar, and divided into ten doses. One of these was given—morning and evening—to children of from one to two years old; two powders, at the same periods, to those from three to five; three powders to those from six to nine; four to those from ten to fifteen, and five to adults. These small doses never produced the toxicological effects of belladonna; in fact, they scarcely exhibited any marked action. In five or six cases Dr. Stievenart observed a rash similar to that of measles; and, in a few other cases, headache, with dilatation of the pupils, dryness of the fauces, and a slight soreness of the throat, but which had no resemblance to that of *scarlatina anginosa*. In all the other cases no sensible or apparent effect resulted from the administration of the remedy. Dr. Stievenart, generally, continued the use of the belladonna for from nine to ten days; in some cases, it was given for fifteen days. He thinks this period sufficiently long to put the system under the influence of the preservative powers of the remedy: but recommends to resume its use if the epidemic returns or breaks out again with renewed violence. In an epidemic of scarlatina which occurred in South Carolina, Dr. Irwin made a very extensive trial of the prophylactic properties of belladonna. Of two hundred and fifty children who were placed under the influence of the drug, less than half a dozen had the disease, and that very mildly. In the families, the members of which were not placed under the influence of the belladonna, the disease occurred with scarcely an exception. Dr. McKee, in the extension of the same epidemic, made use of the belladonna, and derived from it the same protective influence. Dr. Rufus Hammond, of Indiana, also bears testimony in favour of the prophylactic powers of belladonna, based upon ample opportunities for observation.—C.]

LECTURE LXXXIX.

The Plague. Erysipelas. Erythema nodosum. Urticaria. Prurigo. Scabies.

OF that group of *contagious* exanthemata of which I undertook to give you some general account, two only remain to be noticed; viz. the plague and erysipelas.

Concerning one of these, the plague—as I have never seen, and hope never to see it; and as, with Cullen, I “think it unfit for a person who has never seen the disease

to attempt its particular history" — I shall not presume to offer you any observations in detail. It is a very malignant kind of contagious fever; prevailing, at certain times and places, epidemically; attended with a sort of eruption, namely with buboes and carbuncles; and not furnishing, apparently, any sure or permanent security against its future recurrence. In Sir J. Forbes' *Select Medical Bibliography* you will find a long list of works on the plague. I would second Dr. Cullen's recommendation, that you should consult those authors only who have themselves had personal experience of the disease. Among the publications that fall within this rule may be mentioned Dr. Russell's History of the Plague as he saw it in Aleppo; Sir James M'Grigor's Medical Sketches; Sir Arthur Brooke Faulkner's Account of the Plague which occurred at Malta in 1813; Desgenettes' *Histoire Médicale de l'Armée d'Orient*; and Assalini's description of the malady as he witnessed it when in attendance upon the French army in Egypt.

I proceed, therefore, to *erysipelas*. And I wish, in the first place, to fix and define that specific complaint of which *alone* I propose at present to speak. The term *erysipelas* has been employed by medical men in a very loose and vague manner. Any diffused redness and inflammation of the skin is apt to be set down as *erysipelas*; and hence we have disputes as to the distinction between *erysipelas* and *erythema*. But it would tend, in my humble judgment, to the formation of more settled opinions in respect to *erysipelas*, if the term were restricted to that disease in which the integuments of the *face* and *head* become diffusely inflamed. The phrase *erysipelatosus inflammation* may properly enough be applied to other cases, similar to this in so far as the condition of the *skin* is concerned; but in what I should consider true *erysipelas*, in the medical sense of the word, there are other characters belonging to the disorder quite as important as, and more distinctive than, the cutaneous affection. What is usually spoken of as *erysipelas* of the face and head, and what I would call simply *erysipelas*, falls naturally within that group of exanthematous diseases which includes small-pox, measles, scarlet fever, the plague, and continued fevers. It is an idiopathic inflammatory disorder, running a *tolerably regular and definite course*; attended by inflammation of the integuments of the body, or in other words, by an *eruption*; often *prevailing epidemically*; and capable of being *communicated*, under circumstances favourable to its propagation, from one person to another. Its power to protect the constitution from its own recurrence is less certain; but in truth, so many different affections have been lumped together under a common name, that the proper phenomena of true *erysipelas* have not been made sufficiently an object of separate study to enable us to speak with any confidence on this point. I recollect, however, a certain female who has been three or four times my patient in the hospital with *erysipelas*: and one of the night nurses there, whom I treated for that complaint some time ago, is now lying ill of the same disorder under the care of one of my colleagues.

Erysipelas, in the sense now explained, called in Scotland the *rose*, and in this country *St. Anthony's fire*, resembles other disorders of the same group in these points also, that the fever *precedes* the local inflammation, that certain premonitory symptoms frequently go before the outbreak of the disease, and that *sore throat* is an early, and almost a constant, accompaniment of the complaint. The patient feels ill — shivery, feeble, languid, and often drowsy. The actual attack generally sets in with distinct rigors; and the pulse is often very frequent from the first, for many hours, perhaps, before the redness commences. Very commonly there is also manifest disturbance of the alimentary canal, marked by nausea and vomiting, and not unfrequently by diarrhœa. Then some part of the face, usually one side of the *nose*, or one *cheek*, or the rim of one of the *ears*, begins to feel, hot, stiff, and tingling: and upon examining it you find it to be of a deep continuous red colour, and to be swelled and hard. The redness and swelling gradually, and sometimes rapidly, extend themselves: they are defined by a distinct elevated margin; which advances, and invades progressively the neighbouring healthy surface, until the whole of the face, or of the scalp, or of both, is occupied with the inflammation. The lips swell enormously, the cheeks enlarge, the eyes are sealed up by their œdematous and prominent lids, and all traces of the natural countenance are effaced. I know of no disease, except perhaps the confluent small-pox, by which the human face divine is

so completely and speedily deformed and disguised. A stranger seeing a young female in the height of the disorder, and revisiting her after her recovery, is astonished at the change. It seems as if, by some magic process, such as we read of in our nursery tales, a hideous monster has been metamorphosed into a comely damsel.

The inflammation frequently spreads from the face and forehead, or ears, to the hairy scalp; and from the head it travels backwards, in some cases, to the neck and the shoulders. Sometimes—and in this it exactly resembles a scald—the inflamed surface becomes covered with irregular bullæ, or blisters; but often there is *no* vesication. This circumstance, therefore, which has been mentioned by some as furnishing a point of distinction between erythema and erysipelas, fails of that purpose.

In many cases the inflammation is quite superficial: in others it dips, as it were, through the skin, and affects the subcutaneous areolar tissue, and then and there suppuration and even sloughing of that tissue, are apt to take place. We find this to be the case often in the loose tissue of the eyelids; and it is more common on the scalp perhaps than on the face.

After the redness has lasted three or four days, it fades, the swollen surface subsides, and desquamation ensues; and as the inflammation creeps, perhaps, gradually from one part of the surface to another, you may find the face becoming pale, and covered with patches of dead cuticle, while the scalp, or the upper part of the neck, is becoming red. Sometimes those parts of the inflamed surface on which blisters had formed are covered with *crusts*, rather than with merely dead and dry cuticle. In almost all these cases of erysipelas of the head and face, there will be found to be redness and soreness of the *throat* also; although this is not always inquired into, or complained of.

There is considerable variety in the intensity and complication of the symptoms. Sometimes the sufferer lies patiently still, yet apparently conscious and rational, till the tumefaction diminishes, and he is again able to open his eyes. Generally there is some wandering of the mind, especially at night; and in bad cases there is much delirium, and at length complete coma, and the patient dies at the end of a few days. In some of these cases the inflammation has extended to the *encephalon*; in others it is probable that the functions of the brain are disturbed through the febrile derangement of the circulation. When death takes place, and the head is examined, serous fluid is usually discovered beneath the arachnoid, or in the cerebral ventricles; and the veins of the *pia mater* are turgid. I have stated before that I doubt whether such appearances are always to be attributed to inflammation. Sometimes there are no morbid appearances at all within the skull.

It is said that the erysipelas does, now and then, suddenly desert the surface; and that inflammation of some internal part, and particularly of the brain, is apt to follow such rapid subsidence of the external malady. I presume that this metastasis is rare. I do not recollect to have seen it. But the *extension* of the disease, the supervention of delirium and coma, while the external inflammation *continues*, is of common occurrence.

This, then, is one way in which erysipelas is accustomed to prove fatal; by effusion within the head, and *coma*.

And there is another mode in which death is not unfrequently brought about, and which has not been so much attended to; I mean by the affection of the throat. The patient dies sometimes almost suddenly; unexpectedly; you cannot account for the unlooked-for dissolution. But if the throat be examined you may (sometimes at least) there discover the solution of the mystery. The sub-mucous tissue of the glottis and epiglottis is filled with serum, or pus, the chink of the larynx has been nearly or completely closed; and the patient has died of *apnœa*. This is just analogous to what takes place externally: the enormous swelling of the eyelids, and lips, and face, is owing, in a great degree, to serous fluid poured out into the *subcutaneous* areolar membrane.

Another way in which erysipelas may kill, is by gradual *asthenia*. Without any stupor or much wandering, without any marked affection of the breath, the pulse becomes weaker and weaker, the surface cold, and the heart at length ceases to pulsate. This mode of dying is less common in this disorder than the other two.

The causes of erysipelas are various, and often obscure. I have stated that it is

communicable, by contagion, from person to person : yet this contagious property is so feebly marked, that it is denied by many. It is more active at certain times, at certain seasons, at certain places, than at others ; which is the same thing as to say that there are *predisposing* causes of the disease ; that there are influences which augment the susceptibility of the body to the agency of the poison.

I believe that on the Continent they do not allow erysipelas to be contagious at all : but very satisfactory evidence of the fact has been collected by several of our own practitioners. In the second volume of the *Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge*, Dr. Wells has brought together several examples in which the complaint appeared to be unequivocally propagated by contagion. "I visited (says he), on the 8th of August, 1796, in Vine Street, Clerkenwell, an elderly man, named Skelton, who had been attacked several days before with *erysipelas of the face*. In about a week afterwards he died. On the 19th of the following month, I saw a Mrs. Dyke, of about seventy years of age, the landlady of the house in which Skelton had been a lodger, and found *her* labouring under an erysipelas of her face. I inquired whether any other person in her house had been ill of the same disease since the death of Skelton, and was told that his wife had been seized with it a few days after his decease, and had died in about a week. During my attendance upon Mrs. Dyke, an old woman, her nurse, was attacked with the same disorder, and was sent to her parish-workhouse, where *she* died. Mrs. Dyke has since informed me that a young man, the nephew of Skelton, was taken with the disease of which his uncle had died, shortly after visiting him, and survived the attack only a few days. That she herself had been several times with Skelton and his wife during their sickness, and after their death had removed some furniture from the room they had occupied to her own apartment." Dr. Wells relates other histories of the same kind, all occurring when there was no particular *epidemic* of erysipelas prevailing to account for them. Professor Arnott has given some other examples, still more striking, of the propagation of erysipelas from one person to another, not only under the same roof, and in the same locality, but also when the parties lived at a distance from each other, and the intercourse between them had been casual and temporary. These cases are stated, I think, in the fifty-seventh volume of the *London Medical and Physical Journal*. The following incident has been told me upon good authority. A man living somewhere in Westminster fell ill of idiopathic erysipelas. In that state, for some reason or other, he was removed thence : and his brother, who was a servant in or near Portland Place, received him clandestinely into his master's house, and allowed him (for two nights, I believe) to share his bed. That brother was soon attacked with erysipelas ; and in the course of his illness was visited by his master. The master also was attacked ; and it is worthy of remark, that in both master and servant, the disease showed itself just seven days after they had respectively come near another who was affected with it. Dr. Elliotson gives an account of having suffered the disease in his own person. It began in him five days after the breath from one of his patients, over whom he was stooping to examine the skin, and who had erysipelas badly, and died of it, had come upon his face. "I turned away (he says) disgusted, and said, *I hope I have not caught it* ; but five days afterwards, having forgotten the circumstance, I was seized with it." More than once I have had occasion to remark that successive tenants of the same bed in a hospital have been seized with erysipelas after their admission.

But allowing, as I think we cannot but allow, that contagion is one of the exciting causes of erysipelas, there are others which *more frequently* excite it. At least there are many instances of the disorder in which we can trace no exposure to contagion, and in which we can perceive some other probable reason for its occurrence. Sometimes, no doubt, it comes on without any obvious cause. The application of cold often gives rise to it. Irregularity of diet is said to do the same. Violent mental emotions are also accused of being occasionally its cause : it is said to have been brought on both by anger, which is an exciting, and by fear, which is a depressing, passion. It is incidental to what I have called purulent infection of the blood, and in all probability there has been a previous morbid condition of the blood in all those instances of the disorder which appear to be produced by exposure to cold, or by mental agitation. Many cases, not to be distinguished in their appearances and effects from idiopathic erysipelas, result from local injury. I have already told you

that there is no inconsistency or absurdity in supposing that a disorder which originates in some common cause, may be capable of spreading in the way of contagion. And the testimony of Mr. Lawrence (who is not prone to admit of contagion on light grounds) goes to the effect that such is the case with the disease in question. He mentions an instance in which erysipelas of the head and face, which commenced after the insertion of a seton in the neck, appeared to him to have affected two individuals by contagion.

I say that erysipelas further resembles the disorders of the group in which I have placed it, in that it sometimes prevails *epidemicallly*; and on those occasions, like the rest of the group, its occurrence is promoted by all circumstances that tend to debilitate the body: by intemperance; by previous disease; by low spirits and anxiety; by insufficient nourishment; and by foul air. It used to be much more common formerly in hospitals than it is at present; when less attention was paid to cleanliness and ventilation.

Erysipelas is another of the diseases concerning the *treatment* of which there has been, and perhaps there may still be, a most embarrassing difference of opinion. When a student many years ago at St. Bartholomew's Hospital, I observed that in the physicians' wards nearly every case of erysipelas was treated at once with bark and wine; in the surgeons' wards nearly every case with depletion and tartarized antimony. Recoveries took place under both methods; and mutual sneers were not wanting. However puzzling this opposition of opinion was to me at the time, I have since learned to side with the physicians. Not that I hold as commendable the facile, untroublesome method, which prescribes the lavish and indiscriminating use of stimulants in every instance. In this, as in many other disorders, it is our safest and best policy to watch the symptoms very narrowly, and to regulate, and it may be to trim, our practice according to their course and character.

I think, the more you see of this disease the more convinced you will be that it is not to be *cut short* by any particular mode of treatment; that it will run a certain course; and that it will *generally* terminate, sooner or later, by resolution, whether remedies are employed or not. It does not follow from this that remedies are of no use; but it does follow that we are to exhibit them, not with the view of *curing* the disorder, but with the view of *conducting* it safely to its termination. Our objects must be, on the one hand, to repress (if we can) any tendency to the spoiling, by inflammation, of vital organs; on the other, to sustain (if we can) the general strength until the disturbance has passed off.

If you look at the history of erysipelas, and of the notions which have *prevailed* respecting it, you will find that the opinions in favour of giving support, and of abstaining, as much as possible, from the abstraction of blood, greatly preponderate. In the outset of the complaint, if the pulse be *hard*, as well as frequent, and there be much headache, and active delirium, it may be right to take blood cautiously either from the arm, or from the neck by cupping, or by leeches from behind the ears. But (I speak of the disease as it occurs in *London*) the time for this kind of practice is soon over: and whenever it may appear to be requisite, the desired effect must be sought by the abstraction of the smallest available quantity of blood.

In all cases it will be right to empty the bowels at the commencement. A dose of neutral salts, or of rhubarb and magnesia, will answer better, I think, in these cases, than calomel and senna. If you see the patient very early, and if there be any nausea or oppression of stomach, it will be proper to administer an emetic.

In most instances you will soon perceive evidence of great debility: a *feeble* as well as a *frequent* pulse; tremors; a dry and brown tongue often. And these symptoms increase, if you *then* persist in drawing blood. The carbonate of ammonia does great good sometimes in such a condition: and this I am very much in the habit of giving; with animal broths and wine. The bad cases of erysipelas are apt to baffle us all. I am not aware that I lose more of them than my neighbours. Speaking generally, a large majority of my patients get well; but I do not bleed one patient in a hundred, from the arm.

I am bound, however, to set before you the kind of evidence which exists in favour of the bark; or rather of the sulphate of quina, which is what I mean when I speak of the bark.

Dr. Fordyce, Dr. Wells, Dr. Heberden — all men of great sagacity and experience

—recommend the treatment by bark. Dr. Jackson, an American physician, advocates, I see, the same plan. He says, that after a purge, and, if necessary, an emetic, the sulphate of quina should be given in as large doses as the patient will bear; that from twelve to twenty-five grains in the twenty-four hours will generally suffice; and that we may know when the dose is sufficient by a buzzing which comes on in the ears. Dr. Elliotson also—whom I here quote the more willingly because I think he is rather of an antiphlogistic turn than otherwise, in general—says, that he has never seen quina do harm, even in active tonic erysipelas; and that in doubtful cases, when you hesitate whether to bleed and put the antiphlogistic plan in force, or to stimulate and support, the quina is *always* a safe and *eligible* medicine. Dr. Robert Williams, of St. Thomas's Hospital, thinks better still of *wine*, which he gives in *all* cases *from the very beginning*.

Taking the disease as I see it in London, I should say that *many cases* do well with but little care or interference from medicine; that *many also*, but a fewer number than the former, prove fatal under whatever plan of treatment may be adopted; and that many patients are to be saved, by judicious management, who would otherwise die.

The first requisite for rescuing these perilous, yet recoverable, cases, is that they should be perpetually watched and tended. The indications of treatment may alter from one hour to another, and it is only by great vigilance on the part of the medical attendant, and on the part of an intelligent and obedient nurse, that medicine obtains its full chance of bringing the patient through.

After clearing out the alimentary canal, then, I would not be active in either way, unless I saw some plain indication for activity. If the pulse became weaker, and I did not feel sure about the propriety of stimulating, I would give five or six grains of the carbonate of ammonia every four hours, and beef-tea. If the disease went on smoothly under that treatment, well and good. If the powers still continued to sink, I should have recourse to wine, or to both bark and wine; but of the two, I am more friendly to wine; and the patients like it better, you may be more sure of their taking it. If, on the other hand, there were much headache, and the pulse were hard, and the febrile distress great, I should apply a few leeches, and prescribe the tartarized antimony in a saline draught. The bowels should not be allowed to become confined; but the mild aperients are better than the drastic in these cases.

I must not omit to tell you, although as yet I have been unable to put the remedy to a practical test, that the muriated tincture of iron has been very strongly recommended in this disease. I should have no scruple in trying it where there was no great cerebral disturbance. Dr. Balfour, after treating twenty cases with from ten to twenty minims of the tincture every two hours, is so thoroughly satisfied of its efficacy as to record (in the *Monthly Journal* for 1853) his belief that we have now “a certain and unfailing remedy, whether the erysipelas be infantile or adult, idiopathic or traumatic.”

Various external medicaments have been used and recommended for the inflamed part. Putting leeches upon it; puncturing it with needles, or lancets; covering, or surrounding it with a blister, or with the lunar caustic in substance or in strong solution; dusting the surface over with magnesia, or with flour; smearing it with various unguents, and particularly with mercurial ointment; keeping it wet with some cold lotion; or fomenting it with hot flannels.

Now of all these local appliances, that which, according to my own observation, is the most useful, and which affords the greatest comfort to the patient, is the last that I mentioned; fomentation by flannels wrung out of a hot decoction of poppy-heads. But in order to give *this*, also, fair play, it should be *continual*: not used for half an hour, and then intermitted; but it should be one person's business to apply the fomentation assiduously, as long as it is soothing and grateful to the patient. The local treatment most in favour with our apothecary at the hospital is that of covering the inflamed face and head with flour, by means of a dredging-box. The patients declare that the flour cools, soothes, and comforts them. This is a more convenient, and, in some respects, a more eligible, application than that of hot flannels. It is less likely to fail of its purpose through the negligence of the nurse.

[Keeping the inflamed surface constantly covered with perfectly fresh hog's lard,

has a very soothing effect, and tends to reduce the violence of the inflammation. We have occasionally employed an ointment formed of acetate of lead fifteen grains, rubbed up with one ounce of hog's lard, and have been pleased with its effects.—C.]

So much for erysipelas, as it usually comes under the notice and the management of the physician. You are aware that an affection of the skin very similar to that which I have been describing, and called also by the same name of erysipelas, is very common in other parts of the body; on the extremities especially, and occasionally on the trunk: and it will travel sometimes from an extremity till it reaches the head. These varieties of cutaneous inflammation are, in most instances, the indirect consequences of some local injury: of punctured wounds; of the stings of insects, or the bites of venomous reptiles; of mere scratches sometimes. Or the cutaneous inflammation will spread from old sores; or supervene upon dropsical limbs. It is curious that these complaints also are much more apt to occur, and even to multiply by a sort of contagion, or in virtue of some epidemic atmospheric influence, at certain times and places than at others. You will find that there are periods when the surgeons of hospitals dread to perform any operation, lest it should be followed by this spreading inflammation of the skin. There are many points of great interest connected with these diversified forms of what is called erysipelas: they are more liable to be attended with gangrene than erysipelas of the face and scalp: on the other hand, they are more liable also to be complicated with inflammation of the subcutaneous areolar tissue, and with suppuration; and to require incisions to relieve the great tension of the inflamed parts, and to facilitate the escape of the pus, or of sloughy dead portions of areolar tissue: but all these matters belong rather to surgery, and have been discussed, I make no doubt, by the professor of surgery.

[Erysipelas is of frequent occurrence in the earlier period of infancy, and is among the most fatal of the diseases which occur at that period. It very generally terminates in death, especially when it occurs during the first month. Its danger gradually diminishes as the child advances in age, but even when it attacks after the fourth month, the greater portion of the cases terminate fatally.]

The invasion of the disease is always extremely insidious. The child appears somewhat morose; his sleep is slightly diminished, and he sucks rather less than before; with these trifling symptoms, there is associated a small patch of redness upon the pubes, which is painful upon pressure. The redness gradually spreads over the abdomen and thighs, and is, occasionally, disseminated. When the redness extends to the hands and feet, these parts acquire a degree of redness and swelling far greater than that of any other part. The genital organs, in some cases, sphacelate, in consequence of the local inflammation, and in many acquire an emphysematous appearance. In place of appearing first upon the pubes, the erysipelas has been known to extend from the areola of the vaccine vesicle, less frequently from any accidental laceration of the skin or from the excoriations so common in the cutaneous folds of the groin and other parts.

The disease at first appears perfectly local—it is not until several days have elapsed, that general uneasiness and fretfulness present themselves. The colour of the skin, and the expression of the countenance, often remain for some days without exhibiting any striking change, when, suddenly, an ashy cadaverous paleness is observed; the child cries incessantly, there is constant jactitation, and complete loss of sleep. These symptoms are succeeded by deep stupor and death. The pulse is at first frequent, and the heat of the skin sinks only during the fatal stupor which precedes death. Convulsions, diarrhoea, and vomiting are seldom observed. When the progress is such as we have described, peritonitis has occurred—which is, according to M. Trousseau, a frequent disease in children, and one which has not hitherto been accurately described. The duration of infantile erysipelas varies considerably, sometimes being extremely short, in others, on the contrary, being prolonged to the end of the week.

In post-mortem examinations, the cutaneous disease is occasionally the only morbid change detected; but when peritonitis (a frequent complication) has occurred, the umbilical vein is often found inflamed, and filled with pus, as far as the transverse furrow of the liver, while inflammatory exudations are found on the peritoneal surface of the abdominal viscera.

According to M. Trousseau infantile erysipelas is principally observed when puerperal fever prevails in the wards of the lying-in hospitals of Paris. The infants appear to inherit from their mother a *purulent diathesis*, and seem to be still, within certain limits, subject to the same maladies as the mother, whose constitution has so lately been theirs. The peritonitis of the infant may be, therefore, as properly termed puerperal as that of the mother, because its general cause is to be sought for in the circumstances which have accompanied the last stage of child-bearing and parturition. It is natural that the skin should be the seat of disease, from its having been so recently called upon to the performance of functions as new as they are important.

In the infants predisposed to erysipelas, the umbilical cicatrix does not form readily, and the ulceration which results is sometimes the occasional—the local cause—of the cutaneous disease.

Dr. Friebe (*Journal für Kinderkrankheiten*) describes a form of erysipelas which commences about the umbilicus, within a few weeks after birth, and is frequently accompanied with ulceration of the navel, and infiltration of lymph or pus into the subcutaneous cellular tissue, and deposits of a similar nature in the partially obliterated umbilical vessels. It is attended with great and rapidly increasing exhaustion, and occasionally convulsive symptoms of more or less severity. It is most generally fatal; often within the course of forty-eight hours, and without having extended more than three fingers' breadth around the navel.

Dr. Friebe is inclined to view this form of infantile erysipelas as a variety of partial induration of the cellular substance, in consequence of the cachectic condition of the infants in whom it usually occurs, and the peculiar character of the inflammation—while the circumstance of the umbilical vessels being, in fact, converted into fibrous cords, previously to the commencement of the disease, leads him to believe that it cannot arise from the umbilical phlebitis.

We have met very frequently with this form of infantile erysipelas among the children of the poor, and our observations have convinced us that, in the majority of cases at least, it is dependent upon phlebitis of the umbilical vessels; the evidences of inflammation of the latter were unquestionably present in almost every instance in which we have made an examination.

In regard to the treatment of infantile erysipelas, although in those cases in which the disease occurs soon after birth there is but little chance of saving the life of the child, yet when the patient is a few months old, we may do much in arresting the progress of the disease, and conducting it to a favourable termination.

We may remark, however, that erysipelas is always to be considered a dangerous disease during infancy, but more particularly when it occurs in infants of a weakly and unhealthy habit of body.

The bowels should be freely opened by a grain or two of calomel, followed in a few hours by a teaspoonful of castor oil, or a simple laxative enema, and they should be kept in a free condition subsequently, by the exhibition, every three hours, of divided doses of calomel, combined with minute doses of ipecacuanha and extract of hyosciamus—the addition of the latter is calculated to prevent or allay irritation, without interfering with the aperient action of the calomel. When the skin is warm or dry, the liquor acetatis ammoniæ alone, or combined with antimonial wine, will often prove beneficial, as will also the occasional use of the warm or tepid bath.

If symptoms of cerebral disease should occur, a leech or two should be applied to the temples,—cold applications to the scalp,—the bowels should be freely opened by calomel, followed by castor oil, or purgative enemata, and warm sinapised pediluvia should be resorted to.

In a few cases where the parts occupied by the disease are decidedly red and swollen, a few leeches applied upon the sound skin, in the neighbourhood of the inflammation, will often prove beneficial. Much judgment, however, is required, to discriminate the kind of cases which are likely to be benefited by local depletion. As a general rule, a very moderate abstraction of blood will be sufficient.

When a tendency to gangrene is obvious, and the disease assumes a low typhoid character, it will be necessary to resort at once to the use of the carbonate of ammonia, in doses adapted to the age of the patient, and the urgency of the symptoms; and at the same time, the child should be nourished at the breast of a healthy nurse, or if weaned, its diet should consist of animal jellies dissolved in water, beef tea,

chicken water, or sago. It is all important in these cases that the patient be removed to a healthy situation, where he can enjoy the tonic influence of a pure, free atmosphere. When the symptoms of prostration are more considerable, we may combine the use of the ammonia with the sulphate of quinia and extract of hyosciamus.

Should diarrhoea ensue, particularly after suppuration has taken place, it should be immediately checked by the cretaceous mixture, with the addition of tincture of kino and laudanum. When the discharges from the bowels are of a vitiated character, or attended with griping or colicky pains, a few drops of turpentine, three times a day, will be found a very valuable remedy. The turpentine may be combined with the tincture of kino and laudanum.

With respect to the local treatment—washing the inflamed parts frequently with tepid water, or some mucilaginous fluid, will, in many cases, be productive of very great relief to the patient, and occasionally will produce an abatement of the disease; in the intervals, the parts may be dusted with powdered starch, or covered with carded cotton.

When there is decided redness, swelling and tension of the skin, a lotion, composed of a solution of equal parts of the acetate of lead and subcarbonate of ammonia, has been highly recommended. Covering the parts with rags wet with the camphorated tincture, is said to prove often very beneficial. Others recommend a wash composed of a solution of corrosive sublimate, three grains to the ounce of water, or of nitrate of silver of the same strength. It is said that the progress of the disease has been promptly arrested by applying once or twice a very strong solution of the nitrate of silver, by means of a pencil, upon the sound skin, for about an inch around the margin of the inflammation. One of the best applications in cases which exhibit an early tendency to gangrene, is the chloride of lime in solution, in the proportion of half a drachm to a pint of water. Velpeau has employed with advantage a solution of half an ounce of the sulphate of iron to eight ounces of water.

The local remedies just recited are to be employed in the early stages, previous to the rupture of the vesications, and to the occurrence of suppuration or gangrene.

Among the local remedies which appear to be the most generally applicable to infantile erysipelas, is a blister sufficiently large to extend over the inflamed skin, and for a short distance beyond it; after vesication has been produced, the serum should be evacuated, and the vesicated surface dressed with fresh lard. When the erysipelas occurs upon the extremities, a blister applied around the limb, beyond the inflamed surface, will frequently arrest the progress of the disease in that direction. When we have resorted to blisters, which are only proper in the early stages of the disease, we have applied them along the edges of the inflamed portion, partly upon it, and partly upon the sound skin, removing them at the end of three hours, and immediately covering the parts with a soft emollient poultice, with the addition of lard. The most important result which we have derived from the use of blisters is to prevent the spread of the disease.

The mercurial ointment has been strongly recommended in the treatment of infantile erysipelas. It is to be spread on a piece of soft linen, with which the affected parts are to be covered.

In cases attended with an intolerable sensation of burning, we have often derived benefit from the local application of a watery solution of opium.

In a large number of instances, however, no benefit whatever will be derived from any local application. M. Trousseau states that he has tried every imaginable one—ointments, lotions, blisters, even the actual cautery—without suspending the progress of the disease. Three cases only, occurring within the month, has he seen recover under the use of the ethereal solution of camphor, and baths containing corrosive sublimate. The disease is certainly a very unmanageable one when it occurs in very young infants; we have nevertheless seen it in children a few months old in many instances promptly arrested by the remedies already detailed.

Whenever the cellular membrane is involved in the disease, free incisions should be early made, as well to unload the vessels, and relieve the swelling and distension, as to give exit to the purulent fluid and dead portions of cellular structure. The pus, if allowed to remain, will travel beneath the skin, and between the muscles and tendons, and thus increase the danger and extent of the disease. After the incision,

the part should be covered with soft emollient poultices, and kept as much as possible at rest, and in an elevated position.

When the erysipelas terminates in gangrene, washes of a solution of the chloride of lime, of the chloride of soda, of a few drops of creasote diffused in water, or of a strong decoction of black-oak bark, should be immediately employed, or the sphacelated surface may be covered with the charcoal or yeast poultice. A wash of a very strong solution of the sulphate of copper will in some cases arrest the progress of the gangrene.

When convalescence has been established, some light mineral tonic or the mineral acids, largely diluted, should be administered. The child should be allowed a nourishing diet; he should be daily immersed in a warm or tepid bath, and enjoy a dry, fresh, wholesome atmosphere.—C.]

Very closely connected with erysipelas, and continually confounded with it, is *erythema*. It also consists in superficial redness of some portion of the skin; but it is not attended with inflammation of the areolar texture under the skin: nor with vesication; nor, in general, with fever; nor is it peculiar to the face and head.

There are numerous varieties of erythema described by writers on cutaneous disorders, to whom I must refer you for an account of them. Willan and Bateman; Wilson; Willis; Rayer; Alibert; and Bielt, as his practice and lessons are reported by two of his pupils.

The only variety on which I am disposed to say a word, is one which is attended with more or less febrile disturbance. I mean what is called *erythema nodosum*.

This curious affection occurs much more often in young women than in any other persons: sometimes in feeble boys. The eruption is commonly preceded for a few days by indisposition, and some slight degree of fever. Then red elevated spots come out, on the fore part of the legs, and occasionally, but very rarely, on the arms. The redness appears in oval patches, of which the long diameter is parallel to the axis of the limb. They are pretty large patches, an inch and half long, and an inch broad perhaps, and they evidently project and form bumps upon the anterior surface of the leg. From their look, you would suppose abscesses were about to form; but after lasting a few days, the red colour fades, or rather changes to a blue, and the protuberances gradually subside. This eruption seems sometimes connected with disturbance of the menstrual functions. Rayer has seen it occur in connexion with acute rheumatism. So have I. A patient of mine in the hospital was attacked with acute rheumatism of the joints immediately upon the cessation of *erythema nodosum*. In another this order was reversed.

Now I am persuaded that, after an aperient, *rest, the horizontal posture, and quina*, constitute the proper treatment of this affection. I had once a housemaid in whom the disorder appeared, and was attended with unusually high fever, and much indisposition. I treated her, therefore, antiphlogistically; *i. e.*, I kept her on low diet, and gave purgatives; but the disease went on. Fresh knots came out as the old ones faded. At length, I do not remember why, I prescribed some quina for her; and the improvement was immediate, and very striking. She relapsed, however, once or twice, upon leaving off the bark; but by persisting subsequently in its use for some days after she appeared to be well—a permanent cure was effected. Since that time—now nearly twenty years ago—I have seen a good many examples of *erythema nodosum*, and I have treated them all alike; *viz.*, first with an aperient, and then with the sulphate of quina; and they have all rapidly got well. Probably they would have recovered nearly as soon under some other tonic treatment; but I have been so well satisfied with this, since I began it, that I have felt no temptation to try any other.

There is a rash which is well known, and very tormenting, and therefore, not without interest, although it is almost always without danger: I mean *urticaria*. It is arranged by Cullen among the exanthemata; but it does not properly belong to the group to which I would restrict that name, for it is not contagious, and it may happen to the same person a hundred times over. The eruption consists of what, from analogy, are called wheals: *i. e.*, of little solid eminences, of irregular outline, but generally roundish or oblong, and either white or red, or (which is most common)

both red and white; the whiteness occupying steadily the central and most projecting part of the spot, or becoming manifest there when the integuments are put upon the stretch. The rash is accompanied with intense heat, a burning and tingling in the affected spots, and great itching and irritation. In truth, both the appearances upon the skin, and the sensations that attend them, are very much like the appearances and feelings produced by the stinging of nettles. Hence its trivial name, *nettle-rash*: which is, indeed, the same, in meaning, with the scientific appellation, *urtica* being the Latin for a nettle. Similar appearances follow almost immediately upon a smart blow with a cane, or with the lash of a whip, on the skin. Red stripes or *wheals* arise, and within the reddened surface one or more elevated spots of a white colour are visible.

There are two varieties of urticaria: one in which the complaint runs a short course, and soon subsides, and may be considered acute: another in which it is chronic, and either persistent or intermittent. The acute form is attended with feverishness, which sometimes begins two or three days, but commonly not more than a few hours, before the eruption appears; or the fever and the rash may commence together. In most cases, perhaps in all, the disorder is intimately linked with some derangement, manifest or latent, of the stomach, and it may often be traced to the imperfect digestion of particular articles of food. It is very curious that the contact of certain substances with the mucous membrane of the alimentary canal should affect the external tegument precisely in the same manner as the virus of the nettle, and some other irritants, when these are applied to the skin itself. The stomach may be healthy, yet incapable of digesting some particular substance, which then acts like a poison; or it may be habitually weak, and unequal to the digestion of matters which the sound stomach disposes of with ease. The offending articles of food do not produce the cutaneous affection in all persons, nor even necessarily in the same person at all times. But there are some edible substances which are much more likely than others to be followed by nettle-rash. Certain vegetable matters are very apt to excite the disorder in some persons: oat-meal; almonds, especially the bitter almonds; any bitter kernels; particular species of strawberries; raw cucumbers; mushrooms. Some of the vegetable substances used in medicine are known to have, frequently, the same effect; capivi, for example; the cubeb pepper; valerian. Urticaria has been brought on by drinking porter, or, most probably, by some of the drugs with which our porter is sophisticated. These effects are not confined to vegetable substances. Shell-fish is a common source of nettle-rash. I have known it to be occasioned by prawns; crabs sometimes have the same unpleasant consequence; and muscles still more often. An hour or two after some one of these substances has been swallowed, and perhaps much sooner, nausea is felt, and oppression about the epigastrium; the patient becomes giddy, his face and head sometimes swell, his skin begins here and there to burn and tingle, and presently the eruption, as I have already described it, breaks forth. It is attended with intolerable itching and pricking sensations, especially at night, when the patient is warm in bed; or when the affected surface is exposed to the air. Vomiting and diarrhoea often supervene, and prove the natural cure of the attack.

We read that this disorder has sometimes proved fatal; but this must be under very unusual circumstances of weakness in the patient, or of some peculiar virulence in the exciting cause.

The chronic form of the complaint is apt to be very obstinate and teasing. It comes and goes, and comes again. The evening is one of its favourite periods. In those who are subject to it, the itching and the wheals are readily brought on by scratching or rubbing the surface. This is the urticaria *evanida* of Willan. Dr. Heberden had known persons afflicted in this way for ten years together. I have observed nettle-rash to occur in connexion with sudden and violent paroxysms of dyspnoea, resembling asthma fits; so that I could not help suspecting that the mucous membrane of the respiratory passages was irritated after the same fashion with the external skin.

Even the chronic variety of urticaria is, in some instances at least, produced by certain *ingesta*; and the peccant substance may often be detected, and the tiresome malady be cured, by following the simple and judicious plan recommended by Willan; namely, that of instructing the patient to abstain, for a while, from all his customary

articles of diet, one by one, in their turns. This experiment does not, indeed, always answer. The urticaria will sometimes abide, notwithstanding: so that although it probably depends in all cases upon some disordered condition of the stomach or bowels, we cannot say that such disorder is *always* the consequence of something that has been swallowed.

The treatment to be adopted in the acute or febrile nettle-rash, when it depends upon something recently received into the stomach, is that which common sense would suggest, and which nature often plainly indicates. We seek to expel the offending material by an emetic, and by purgatives: and this being done, the cure is completed. In the more chronic and recurring varieties, we endeavour, in the first place, by making the experiment recommended by Dr. Willan, to detect, that we may thenceforth interdict, any article of diet which may have caused the disorder. If we fail in this attempt, our object must be to correct that faulty state of the digestive organs, or to neutralize that inbred poison, upon which the cutaneous affection depends. Laxatives and antacids are found to be the most successful means of attaining these ends. They may be given together, or separately. A few grains of rhubarb taken daily just before breakfast, and just before dinner, have cured a chronic case of long standing. Or rhubarb and magnesia may be taken together; the carbonate and sulphate of magnesia; castor oil. The snake-root has obtained some repute as a remedy for urticaria. You may prescribe, therefore, if you please, a scruple each of the carbonates of magnesia and of soda, in the infusion of serpentaria.

External applications seem to be of but little avail in this disease; and those which do appear to be of service, act uncertainly, and produce different effects in different persons. The warm bath sometimes gives ease in the severer cases. In the more chronic form of the disorder, spirituous washes, vinegar, sea-bathing, are things to be tried. And cases are related in which, when every other expedient has failed to give permanent relief, removal to a warmer climate has been successful. Dusting the itching surface with flour has, in my experience, afforded much temporary comfort. Still more useful perhaps is a lotion (first recommended by Wilkinson, in a little work on skin diseases) composed of a drachm of the carbonate of ammonia, a drachm of the acetate of lead, and eight ounces of rose water. Its efficacy may be increased by the addition of half an ounce of laudanum.

I should add, that Dr. Elliotson has found *bleeding* very efficacious in relieving patients affected with acute or febrile urticaria. And you may have recourse to the lancet if the patient be strong and plethoric, and his pulse warrant it; and if he be so impatient of the irritation as not to be willing to wait the effect of other treatment, which would probably be quite as effectual, though not quite so rapid.

Prurigo — itching — is a cutaneous affection bearing some analogy to urticaria, at least in the sensations which accompany it. And a most terrible and melancholy affection it often proves to be. Sometimes the parts of the skin which are the seat of the itching do not present any perceptible deviation from the condition of health; but in the majority of instances, you will find, upon close inspection, that they are covered with papulæ, which are nearly of the same colour with the skin itself. Willan therefore places prurigo in the order of Papulæ. He describes several varieties of this troublesome complaint: prurigo *mitis*; prurigo *formicans*; prurigo *senilis*. The torment experienced by patients suffering under the severer forms of the malady is scarcely describable; they scratch and tear themselves incessantly till the blood flows, their sleep is broken, and their lives are rendered perfectly miserable. Sometimes this itching is diffused irregularly here and there over the surface; sometimes it affects the extremities only; and frequently it has a still more limited habitat, occurring round the anus, when it is called prurigo *podicis*; or on the scrotum, prurigo *scroti*; or, worst form of all, the prurigo *puerendi muliebris*.

All these forms of prurigo are apt to be aggravated by heat, and by exposure to the air; they are, therefore, especially distressing when the patient undresses and goes to bed. The scratching tears away the summits of the papulæ, and some watery fluid mixed with blood escapes, and concretes into small thin, black scabs. In the prurigo formicans, the itching is combined with other painful and disagreeable sensations, which different patients describe in different terms: the feeling is like the

creeping of ants, or the stinging of insects, or as if hot needles were thrust into the skin. The *prurigo senilis*, occurring, as that name implies, in old persons, is usually very obstinate, and often effectually destroys all comfort for the rest of the patient's life.

In such cases as I have now been mentioning, great care should be taken thoroughly to cleanse the surface of the body: and the diet should be rigidly plain. All kinds of rich sauces, hot condiments, pickles, and indigestible substances, should be peremptorily forbidden. Various local applications have been praised; but they are, in most cases, used in vain: vinegar, lime water, decoction of *dulcamara*, lotions composed of prussic acid in an emulsion of bitter almonds, a dilute solution of creasote, decoctions of *stavesacre*, and of *digitalis*, ointments containing mercury, tar ointment, and a hundred others. In one instance lately, where the ingenuity of another practitioner had been fruitlessly exhausted, I was fortunate enough to effect perfect relief by smearing the itching surface with an ointment containing a small quantity of aconitine. Mr. Gabb has found a weak dilution of the *Liquor Sodæ Chlorinatæ* very serviceable. Of internal remedies, sarsaparilla, alkalies, arsenic, the iodide of potassium, *dulcamara*, are the most hopeful. When these means fail, opium is our best, and indeed our only resource.¹

The local forms of *prurigo* are frequently connected with local disease, and are most likely to be relieved by measures directed against the primary disorder. *Prurigo podicis* is sometimes dependent on the presence of ascarides in the rectum. The same troublesome affection is not an uncommon symptom of internal piles: and it sometimes accompanies stone in the bladder.

The *prurigo pudendi muliebris*—itching of the genitals in females—is sometimes so constant and tormenting, and the impulse to scratch the itching part so urgent, as to drive the unhappy patient from society. It even gives rise, in some severe cases, to nymphomania. It may proceed from leucorrhœa: it is frequently a sign of uterine disease. It most commonly affects women in whom the menstrual discharge has ceased to appear.

[We have met with it just as frequently in the menstruating female as in those in whom the period of menstruation had ceased. Some females are troubled with it during pregnancy, but at no other period.—C.]

I have never had an opportunity of trying the aconitine in such cases. One local application which has been found very serviceable is the *yellow wash*, which, as you probably know, is a solution of corrosive sublimate in lime water, in the proportion of a drachm to a pint. A saturated solution of borax, first recommended, I believe, by an American physician, Dr. Dewees, has also much testimony in favour of its efficacy.

You will sometimes be consulted—at least I have been, on more than one occasion—about itching of the pubes and scrotum, produced by the presence of the pediculi that are vulgarly called crab-lice. The patients are sometimes quite unaware of the cause of the itching. You may relieve them by the wash I have just mentioned; or, by a more elegant lotion, made by dissolving corrosive sublimate in a little spirit, and adding rose water. A single washing with such a lotion will destroy the whole colony: and the vermin become much more visible after this violent death, turning black, and relaxing their hold upon the skin.

¹ Since the republication of these lectures in America, I have been favoured by Dr. Bowling, of Adairville, in Kentucky, with an account of a plan of treatment which he has found eminently successful against this most distressing malady, and which ought, therefore, to be made generally known. I extract that portion of Dr. Bowling's obliging letter which relates to this subject:—

"I have, in the last fifteen years, prescribed for a great number of cases of *prurigo senilis*, and I can say, with a most rigid adherence to truth, that I have not failed in a single instance to effect a permanent cure.

"I direct that the affected parts be sponged for a minute or so with good apple vinegar, and then be allowed time to dry. After this they are to be smeared over with the citrine ointment (*unguentum hydragryri nitratæ*). The applications are to be made twice a day. The cure is usually effected in a week. I have never known the constitutional effects of the mercury to be developed in this treatment, save in a single instance, and then but very slightly."

Prurigo is a convenient generic name for these cutaneous affections, of which the prominent feature is the teasing sensation that accompanies them. But, besides all these, there is a specific disorder, which, from the intensity of that sensation, is emphatically termed *the itch*, and which deserves a short notice; for it is exceedingly common, and exceedingly distressing, and (what is more interesting still) it is easy of cure. It is one of the very few complaints for which we possess a specific or infallible remedy.

Scabies, or the itch, is, as everybody knows, contagious; but it is contagious only in that particular sense which implies contact. It is not producible by any effluvia which the atmosphere can convey: it requires, for its propagation, that the healthy person should touch the diseased person, or some substance which has been in contact with his unhealthy skin. Certain parts of the skin are more liable to it than others. It is most common at the roots of the fingers and thumbs, between them, as it were; on the wrists; between the toes; in the flexures of the joints. It may spread to almost every part of the trunk or of the extremities; but all observers agree in stating that it is seldom or never seen upon the face and head; a curious but unaccountable exemption.

The eruption is at first papular and then vesicular, presenting a number of pointed watery heads. When the inflammation is aggravated by intemperate habits, or by the scratching from which the patient is unable to refrain, the vesicles are liable to be converted into pustules: and this has needlessly been made a separate *species* of itch, scabies *purulenta*, pocky itch: you see large pustules, filled with a yellow viscid matter, standing on an inflamed base. If you are not aware of these varieties and changes, you may make unlucky errors of diagnosis: affront your patient by telling him he has the itch when he has it not; or suffer him unconsciously to betray and shame himself by communicating it to others, when he has. You will easily understand how it has come to be considered a disgrace to have the itch: for it is fostered and propagated in most unfashionable places, amidst poverty, vulgarity, and filth. Yet the most delicate and high-bred lady may contract the distemper; and when once it is contracted, it will go on indefinitely, through life, unless proper means are adopted for its cure. It never gets well if left to itself.

The most curious point in this discreditable malady, is its connexion with a peculiar insect, called accordingly the *acarus scabiei*. The existence of this ectozoon had long been affirmed and denied; but the vexed question has at length been set at rest by the public demonstration of the acarus, by a M. Renucci, to a number of medical practitioners in Paris. It has since been often detected and exhibited here. Dr. Nevinsou assured me that he furnished Shaw the naturalist, Dr. Wollaston, and others, with living itch-mites for examination, more than forty years ago. It is described, and its form is depicted, in a letter written by Dr. Bonomo, and communicated to the Royal Society, by Dr. Mead, in the year 1703. One reason, probably, why it has often been searched for in vain is, that the acari are not equally numerous with the vesicles; there is not an insect for every vesicle. Another reason is, that the hunters have not known exactly where to look for the insect. It is not *in* the pustules or vesicles, but *near* them; at the extremity of a short, small, superficial tunnel or furrow which runs from them. A third reason why the insect had so long and so often escaped detection, is to be found in its minuteness. It is barely visible by the naked eye; but under the microscope it is seen to be a most formidable monster, in outline like a tortoise, and having eight legs. I show you here its portrait; not in little, but enormously magnified. I hope to procure for you the privilege of seeing the creature itself. The first that I can catch I will ask Professor Rymer Jones to show you by means of his microscope.

There is good reason for believing that this parasitic animal is, not merely a casual companion, but the veritable cause, of scabies. Various attempts have been made, and made in vain, to produce the disease by inoculation of the fluid from the vesicles. On the other hand, transportation of the acarus has always excited the eruption.

These facts explain how it is that the itch, though readily communicable by direct contact, or by fomites, is not communicable through the medium of the air; that fomites long retain the contagious property; and that the disease is curable by whatever destroys the acari. I believe that the complaint called *the mange*, in dogs,

camels, and sheep, has the same, or a similar origin : and I think it extremely probable that certain other varieties of prurigo or pruritus, in the human subject, may depend upon a like cause.

Now *sulphur* is as sure to cure the itch, as quina is to stop an ague. I presume that it kills the acarus ; but whatever may be its *modus operandi*, I have never known it fail to remove true scabies. It is applied externally ; and the only objections to its use are its disagreeable smell, and the dirtiness that belongs to ointments ; but these inconveniences are far outweighed by its certain efficacy. Although many substitutes for this substance have been recommended, I premit them all, and advise you to employ the sulphur ointment, of which you may disguise the smell by the addition of a little bergamot, and the colour by intermixing a small quantity of vermilion.

The ointment should be carefully rubbed all over the skin, at bed-time, and most especially on parts visibly affected with the eruption. The patient should sleep enveloped in a flannel dress. The rubbing should be repeated night and morning, and in two or three days the complaint will be subdued. Then, thorough ablution with soap and warm water, and the destruction of the contaminated clothes by fire, will complete the purifying process.

LECTURE XC.

Herpes; Eczema; Pompholix; Lepra; Psoriasis; Impetigo; Boils; Carbuncle; Purpura; Scurvy. Conclusion of the Course.

If you look at the list of *genera* and *species* appended to the various works which treat exclusively of cutaneous diseases, you will find that they are exceedingly numerous. But these disorders differ widely in their relative importance : and the principles upon which their remedial management proceeds are not so greatly diversified as these “ tables of contents ” might lead you to suppose. I have spoken pretty fully of the most serious and interesting of these maladies — I mean of the febrile exanthemata ; but I have no time left for pursuing in detail the host of chronic affections to which the human skin is subject. Nor do I much regret this. To become expert in the diagnosis of these blemishes, and in curing such as are curable by our art, you must see them with your own eyes. Verbal descriptions of their changeful characters are of comparatively little service or interest. They are among the things that require to be “ *oculis subjecta fidelibus*.” Even pictured representations convey but an inadequate notion of the morbid appearances they are designed to portray. The lecturer on skin diseases should have actual patients before him, to whose bodies he could point.

In this, the final lecture of the course, I can do no more than offer you a few very cursory remarks upon some of the genera into which nosologists have distributed this class of disorders : and I may premise, that the treatment of the genus includes for the most part that of the species.

Vesicles are, as you know, small transparent elevations formed by a drop of aqueous fluid effused beneath the cuticle. Sometimes they are thinly scattered over the surface ; sometimes collected into clusters ; sometimes situated on a red patch of skin ; sometimes quite free from redness. The whole crop comes out at once in some cases ; in others the vesicles appear in irregular succession. They terminate also in various ways : by the reabsorption of the liquid, and slight desquamation ; by the giving way of the cuticle, and the formation of little scabs, under which new cuticle is generated ; and sometimes, though rarely, by ulceration.

Of the vesicular class of cutaneous disorders I have already described the three most important ; namely, cow-pox, chicken-pox, and the itch.

Another not uninteresting genus of this class is *herpes*. This is a transient non-contagious eruption, consisting of red patches of irregular form and variable size, upon each of which stands a crop of vesicles. The eruption runs a definite course; and its several periods—its beginning, its increase, its acme, and its decline—are completed, when its progress is not interfered with, in about ten days. These characters, once known, are easily recognized; and it is of importance that you should recognize them. Not that the disorder itself is of any great moment; nor that it is at all under the influence of remedies; but because it may be confounded with some graver malady. For example, *Herpes præputialis* is a very common and a very trifling species, affecting the foreskin; but it might readily be mistaken for the result of the poison of syphilis, and so cause much alarm and distress to the subject of it, and entail upon him perhaps a needless course of mercury, and bring unmerited suspicion upon the person with whom, whether lawfully or unlawfully, he might have been connected. It has nothing whatever to do with sexual intercourse; and it requires no treatment beyond cold abluition, and the interposition of a piece of lint between the prepuce and the glans penis. In like manner another species, *Herpes circinatus*, the vesicular ring-worm, is liable, when it appears upon the hairy scalp, to be mistaken for that pest of schools and of school-boys, the *favus confertus*, or *porrigo scutulata* of Willan, the common scald-head; a complaint which is naturally shunned as filthy, stubborn, and contagious: and which is in fact a vegetable parasite. *Herpes iris* is a mere curiosity. In this species each group of vesicles is surrounded by four concentric erythematous rings, of different shades of colour. The rings form and fade in succession, one after another, by a slight extension outwards of the inflammation each time. The spots constituting the eruption have been likened to small parti-coloured cockades. But the most singular species of all, and the only species of any serious importance, is the *Herpes zoster*, in which the separate patches lie in the direction of a band that encircles half the circumference of the body. Hence its names, *zoster*, *zona*, *zona ignea*, and in our vernacular tongue, *the shingles*; and even this Dr. Johnson derives from the Latin, *cingulum*, a girdle.

Most commonly the zone is confined to the trunk of the body; has a somewhat oblique direction like a sword belt, and occupies exactly one-half of the circle, lying between the linea alba and the spine, on one side only. Sometimes, however, it extends from the trunk to the limbs. Thus it may begin in the loins, pass obliquely across the flank, and terminate at the inner part of the thigh. Or it may commence from the upper part of the spine, cross the shoulder, and end on the arm or forearm. In the year 1833 I saw a lady affected with this strange eruption, in whom the clusters of vesicles began near the spine in the neck, passed over the scapula, then to the shoulder and axilla, whence the main line ran along the outer side of the upper arm till it reached the elbow, where it turned inwards, followed the inner side of the forearm, went across the palm of the hand, and terminated by two or three patches upon the palmar and inner side of the ring finger. Very rarely indeed it appears on the limbs only. Twice I have seen it limited to the thigh and leg, and in both cases its track corresponded with the course of the sciatic nerve. Thrice I have known it spread from the neck, behind, up into the hairy scalp: and in one of these instances a patch fell upon the conjunctiva of the right eye, of which the vision was for some time in jeopardy. The most common situation of the demi-cincture is across the base of the thorax. It is a curious feature of this curious disorder, that, in nineteen cases out of twenty, according to Bielt, it occupies the *right* half of the body. Of this singular preference of the right side, if indeed it be a general fact, I can give you no explanation. I have seen fifteen cases of the complaint since I began to attend to that circumstance, and in ten of these the eruption was on the right side.¹ Rayer, in the first edition of his book, said that eight cases in ten would be found to be on that side; but a longer experience has reduced that proportion. Of fifty-three examples seen by himself, thirty-seven only were on the right, and sixteen on the left. Reil states that he has *always* observed it on the left half of the body; and Mehlis, among twenty-five patients, counted sixteen in whom the left side was affected. This statistical point remains therefore to be settled, if it be worth settling, by a larger induction of

¹ Since this was written many more cases of shingles have come under my notice, but I am sorry to say that I have mislaid the memoranda which I had made of the positions of the patches

particular cases. The zone seldom transgresses the median line at either extremity, unless perhaps the redness of the extreme patches may extend a little further. It is said, however, in some exceedingly rare instances, to complete the circuit of the body. There is a vulgar but erroneous notion, that the eruption proves fatal when it thus encircles the whole of the trunk; and this notion is as old as the time of Pliny, who says, "*Zoster appellatur, et eneaeat si einxerit.*"

The most important, because the most distressful, of the symptoms, is an intense darting pain, described by the patients as being deep-seated, very acute, and shooting through the chest. Fortunately, however, this is by no means a common incident. At least so I formerly thought, and such is the tenor of recorded experience. Yet within the last three years these sufferings have occurred in five or six of my own patients. Sometimes the pain precedes the eruption; more often it accompanies it; and it is apt to last, in spite of remedies, for some time after the eruption has disappeared. Mr. North tells me that, in a female patient of his, this pain continued to be severe and intractable for eighteen weeks. In two instances I have myself known it last for two years; and in one of the two its severity had scarcely abated in that long time. That this is, however, a rare complication of the disorder, we may conclude from the experience of M. Bielt, who never once witnessed this symptom in more than 500 cases of shingles. The severe and intermitting character of the pain, and the peculiar direction of the row of herpetic patches, lead to the belief that the whole malady may arise from some fault in the nervous system. I may mention some other curious circumstances which seem corroborative of this belief. One of the three patients in whom the scalp was affected with the herpetic patches, had been plagued for seven years with continual noises in his head. Upon the breaking out of the eruption these noises ceased; and remained absent for a year and a half: then they returned. Another person who had an attack of shingles in February, suddenly lost a cough which had teased him all the previous winter. In July, 1855, I was asked to see an elderly maiden lady, who in a former part of her life had had ague, and neuralgia. Shingles had appeared on the left side of her body two months previously to my visit. A demi-circumference of patches, which almost touched each other, extended from one mesial line to the other. But besides this row, there were scattered spots of herpes, not linear in their direction, on the right side of her body, on the shoulder, in the arm-pit, and one on the right thigh. She had suffered and was suffering intense neuralgic pains in the track of the belt, just along the edge of the left ribs. Any cold fluid taken into her stomach would excite the pain at any time; but it often occurred spontaneously. The right half of this patient's body was sometimes warm and perspiring, while the left was chilly, shivering, and affected with horripilation. The neuralgic pain had somewhat of a periodical character. On one occasion it was banished for twenty-four hours by half a scruple of quinia. But the quinia so disturbed her head that she would not repeat it, although various other remedies had been tried in vain.

Of the cause of herpes zoster we have no certain knowledge. It is said to attack young persons more especially, and those who have fine and delicate skins, and the male more frequently than the female sex. But I suspect that these assertions rest on a very loose foundation. Of the fifteen cases already mentioned, ten occurred in females. One of the patients was a child two years and seven months old; another was an aged man of about seventy-five. In several instances I have found upon inquiry, that the patients, being children, were in the nightly habit of wetting their beds. Whether this has been any thing more than a casual coincidence, I do not know; but my attention was first directed that way, some years ago, by Mr. Wheeler, the apothecary at St. Bartholomew's Hospital, who told me that he had often noticed the same circumstance. According to Bateman, the disorder "seems occasionally to arise from exposure to cold after violent exercise. Sometimes it has appeared critical, when supervening on bowel complaints. Like erysipelas, it has been ascribed by some authors to paroxysms of anger." Schwartz saw three cases which followed violent fits of passion; and Plenck affirms that he had known it occur twice after furious anger—and a copious potation of beer.

The duration of the eruption is from ten days to a fortnight; but it is liable to be considerably prolonged by troublesome ulceration, whenever the vesicles and crusts are prematurely chafed off by friction or pressure.

Very little, as you must perceive, can be done, or is requisite, in the way of treatment. The patient is to be cautioned against rubbing off the heads of the vesicles. Attention should of course be paid to the state of the stomach and bowels; and the diet should be regulated. Our main business is to look on, and to endeavour to set right whatever function may be manifestly wrong.

Should the eruption be attended or followed by the intense shooting pain which sometimes, but not very often, harasses the patient, it will be right to apply opiates, by friction, over the affected region. I would use the aconite ointment in such a case. Warm baths will also be proper; and as the pain is probably neuralgic, the carbonate of iron is a remedy which ought to be tried.

Eczema is another genus of the vesicular class of diseases. It is characterized, in its commencement, by an eruption of very minute vesicles, scarcely prominent, closely crowded together, and requiring a microscope sometimes to render them distinctly visible. They terminate either by the reabsorption of the fluid they contained, or by the formation of superficial moist exoriations. *Eczema* is not contagious.

There are several species or varieties of this form of cutaneous disorder also. It is sometimes produced by great heat, and particularly by the heat of the sun; and this is named *eczema solare*, *heat-spot*; sometimes by the contact of irritating substances with the skin, as in what is vulgarly called the grocer's itch, affecting the hands of those who are much conversant with sugar. *Eczema* often occurs upon the scalp, and constitutes, I believe, the most frequent form of what is commonly named scald-head, *porrigo*, or *tinea capitis*. But the most severe of all its species is that which has received the names of *Hydrargyrium*, *Erythema mercuriale*, and *Eczema rubrum mercuriale*. This, as these names imply, is an occasional consequence of mercury; an unusual consequence, no doubt, and one that happens only in a few peculiar constitutions; but you ought to know it, in case it should follow the use of mercury prescribed by yourselves.

The eruption begins usually in the groins and upon the thighs. It is at first red, and is accompanied by much heat and itching. It soon extends, in the severer cases, over the whole body; and an innumerable multitude of very minute glittering vesicles may be seen, with the aid of a magnifying glass, from the beginning. Like that of erysipelas, the eruption is attended with a good deal of swelling. The intumescence of the face is such as to close up the eyes: and the disorder becomes febrile, in its course; for there is seldom much fever at the onset. The vesicles increase in size, turn milky, burst, and pour forth an acrid exudation, that irritates and inflames the skin with which it comes in contact, and thus increases the local complaint. The distress and worry occasioned to the patient by the fœtid smell of the discharge, by the stiffening which it causes of his body-linen, and by the heat and itching, are, I conceive, the main causes of the febrile disturbance. The discharged matter is apt to become thick and hard, and to present the appearance of large scabs: and in this state the nature of the disease may very easily be misunderstood, it being impossible to say, when it is seen for the first time under these circumstances, whether it was originally vesicular or not.

The duration of this harassing distemper is variable. It may be over in a fortnight, or it may last several weeks. It terminates by the cessation of the discharge, and then the cuticle detaches itself in large flakes. Sometimes in this disease also the epidermis falls entire from the hand, like a glove.

Without being dangerous to life, this disorder is apt to be obstinate. It is not much within the control of remedies. What little can be done is chiefly palliative. The mildest local applications must be used: tepid water, barley-water, strained gruel. The warm-bath, when circumstances permit. Poultices are sometimes of much service, in preventing the hardening of the matter that exudes, and so obviating one source of irritation. Flour, or powdered charcoal, may be sprinkled over the eruption in the slighter and early cases, for the purpose of absorbing the discharge. Equal parts of olive-oil and lime-water make a soothing liniment, which may be applied by means of a feather. The local remedies may fairly be varied, for sometimes one is found to give relief, and sometimes another. The patient's linen must be frequently changed, especially whenever it becomes stiff and hard with the exudation.

With respect to the general treatment, opiates to procure rest, and to allay irri-

tation, are probably indispensable. The bowels must be kept moderately open, but no severe purging should be employed, for the patient must at all events undergo a long and weakening process, and therefore it must be our care that the *treatment* be as little weakening as possible. In protracted cases, where there is much exhaustion, wine may with propriety be given; and, almost always, good strong broths. As the disorder declines, some of the reputed tonics may be prescribed; the mineral acids, quina, sarsaparilla.

I need not say that, in such cases, you must be scrupulous in seeing that no more mercury be administered or applied.

Eczema, spontaneous in its origin, is a very common, and a very teasing complaint among children. Mr. Erasmus Wilson, after large experience in treating it, expresses his confident belief that almost every case of *eczema infantile* admits of a ready cure. His method is to give calomel at moderate intervals, with the view of clearing and regulating the digestive organs. This preparatory treatment is followed by the administration of arsenic in small doses, as a tonic, internally, and by the external use of well-prepared oxide of zinc ointment.

In many children thus tormented with eczema, I have remarked that the rapid departure, or even the sudden diminution, of the eczematous eruption has been immediately succeeded by wheezing in the chest, and oppressed breathing; which in their turn have subsided upon the re-appearance of the eruption. This alternating affection of the tegumentary membrane and of the mucous membrane of the air passages, has sometimes made me dread the curing, so earnestly desired by mothers, of the unseemly disorder of the skin. Mr. Wilson believes that no such dread need be entertained, when the cure has been preceded by a due course of calomel.

A separate class of cutaneous diseases, very analogous, however, to that which we have been describing, is the class of *bullæ*, or blebs. Anatomically speaking, there is but little difference between the two: *bullæ* are *large vesicles*. When the eruption is at its height, it is composed of hemispherical prominences of various sizes, from that of a pea to that of a hen's egg, and having the shape and appearance of the bubbles raised in a pool of water by a hard shower of rain. They are formed by the effusion of a serous, or a sero-puriform fluid, between the true skin and the cuticle. You can only be sure of the diagnosis when you see the eruption in this stage of its progress.

The best example of this class is that which is called by some writers *Pemphigus*, by others *Pompholix*.

It is characterized by the presence of *bullæ*, varying in their magnitude, commonly distinct, but numerous, springing up in successive crops, on one or more parts of the surface. At first these *bullæ* are nearly transparent, and contain a thin limpid serum; but they become gradually opaque, pearl-coloured, and ultimately many of them acquire a reddish tinge.

Pemphigus has been described as being sometimes acute, sometimes chronic. The acute form is attended with smart fever, the *bullæ* rise spontaneously or in quick succession, run their course, and disappear; and then the disease is over. This is a very rare form. In general the *bullæ* continue to come out; the complaint is spread over weeks, or months, or years; and it is accompanied by little or no febrile reaction. This, on the other hand, is a common form of disease. It is the *Pompholix diutinus* of Willan and Bateman. The eruption often occupies all parts of the body at the same time, or in succession: in other cases it is confined to a limited space. I have most frequently seen it on the fore-arms and legs. When the *bullæ* are very numerous, they may give rise to some febrile symptoms, but not else. The complaint may be indefinitely prolonged by successive crops.

The eruption begins in small red points, the formation of which is attended with a slight pricking sensation. Some patients have likened this sensation to that which accompanies the passage of the electric spark. In the centre of each of these spots, the cuticle becomes lifted, while the circumference of the spot enlarges, so that *bullæ* are rapidly formed, often in the space of a few hours only, as big as a hazel-nut, or a walnut: or the blebs may even be much greater than that. Either in consequence of their distension, or of the pressure made upon them by the movements of the patient, some of these *bullæ* burst, and a straw-coloured serum exudes. Then the

epidermis collapses into folds and wrinkles; or if it be detached at a part of the margin of the bulla, it is rolled back, so as to expose a portion of the red, painful, and smarting surface beneath it. Towards the third or fourth day, when the bullæ lose their transparency, and the liquid they contain becomes reddish, those bullæ which have not been broken sink down and wither; the cuticle is no longer stretched; but, sodden by the serous fluid, it assumes a whitish hue, becomes opaque, and forms at length small brownish flat crusts, of no great thickness.

In the meantime fresh bullæ appear by the side of the former ones, and pursue the same course; so that generally you may see in the same person, tense bullæ containing a transparent and yellowish serum; thin crusts; and irregular patches of various sizes, slightly excoeriated.

This is the ordinary course of chronic pemphigus: and I say it may thus go on for months or years.

The disease is most frequently observed in persons of debilitated habit. It is sometimes apparently the result of intemperance; or of the use of bad or insufficient food. In Biett's experience it has often been coincident with the fatty liver. When the disorder is chronic and uncomplicated, the treatment found useful is such as we might expect benefit from, knowing the constitutions in which the disease is most apt to occur, and the causes which seem at least to favour its occurrence, if they do not produce it: regulation of the bowels; good nourishing food; tonic medicines, bitters, and especially quina and the mineral acids. Biett declares this kind of treatment to have been very successful in St. Louis; and that, not only in old and worn-out subjects, but also in the young, especially when the complaint has been chronic. Bateman recommends the same general plan.

Local applications have seldom been much employed, except some mild ointment to the excoeriated parts. Biett advises emollient lotions, or even opiate washes when much irritation exists; but a case recorded in the *Medical Gazette*, by Dr. Graves, of Dublin, affords a remarkable instance of a cure by local applications alone: and it is a case worth recollecting, although, as he justly remarks, we ought not to generalize from a single instance.

His patient was a boy, fourteen years old, of slender frame and delicate constitution, yet enjoying uninterrupted health, except the cutaneous disease, which had lasted five years. During that time the succession of bullæ had seldom ceased. The bullæ were very numerous, occupying not merely the face and extremities, but the trunk also: and they were in various stages of their progress, some healing after having burst, some of a larger size and unbroken, others small, and recent.

Dr. Graves observes, that from the descriptions of Bateman, and of Biett, although both authors describe it correctly, we should scarcely form a notion of the occasional severity of this disorder. He had seen two examples of it in young men, where the irritation and suffering produced by the constant exposure of large portions of skin denuded of epidermis, had operated most unfavourably on the general health, almost banishing sleep, and reducing the patients to a state of great debility. These cases did not yield to the methods of treatment recommended by authors; and, therefore, Dr. Graves determined, whenever another opportunity should occur, to have recourse to a new plan.

In the boy in question, therefore, he had all the bullæ opened with a lancet, and the denuded surface of the corium was then touched with a stick of lunar caustic. The nitrate of silver was also applied to the skin around each bulla, for the breadth of a line; and the recent pimples, which indicated the formation of future bullæ, were all treated in the same way. The boy was then washed, and supplied with clean linen.

This single application of the nitrate of silver had not merely the effect of entirely destroying the morbid action in the portions of the skin which were at the time affected, but (what was very remarkable) no fresh bullæ made their appearance afterwards: none at least had appeared for four months, when Dr. Graves wrote his account. The only part where a repetition of the process was required, was the palm of the hand, where the thickness of the cuticle rendered it more difficult to expose the diseased surface of the cutis to the full action of the caustic.

It might strike you from this cure of a long standing disorder, so readily, by mere local means, that the disease propagated itself from one part of the surface to an-

other, by a sort of re-inoculation. But it has been fully proved that the disease is not contagious. A Mr. Gaitskill engrafted himself, with impunity, with the fluid; and analyzed it, and found it apparently like the thin serum of hydrocephalus. Dr. Graves, therefore, supposes that the cure was owing to the simultaneous destruction of all the parts of the skin that were in a state of morbid action: a morbid action which would have been otherwise propagated to other portions of the surface, by what is called the sympathy of *continuity*.

The class of scaly eruptions—the *squamæ*—is distinguished by the occurrence of red spots or blotches, upon which laminae of altered cuticle form, and are thrown off, and constantly renewed. You will perceive that, anatomically, this class of cutaneous disorders has a close analogy with the rashes; and yet it is separated from them by very obvious particulars. In the exanthemata of Willan and Bateman, the redness is *followed* by desquamation; in the *squamæ* these two appearances co-exist: in the exanthemata the sequence of redness and desquamation takes place, in general, once only; in the *squamæ* the morbid cuticle continues for an indefinite time to scale off again and again, in successive fragments, from the abiding red patch of skin.

Lepra, psoriasis, and pityriasis, and some syphilitic eruptions, constitute the principal of the squamous affections.

Lepra is a very common disorder of this class; hence its name, *lepra vulgaris*. It consists in red scaly patches, of various dimensions, but always affecting a circular or elliptical shape, and scattered over different parts of the body. It commonly begins on the limbs, most usually near the joints; just below the knees, or the elbows; and Dr. William Budd has pointed out the curious fact that these patches, especially when they are few, and the disease is recent, are distributed symmetrically, each spot on the one limb answering in situation to a similar spot on the fellow limb. This shows that the disease is a blood disease; that it depends upon some poison, introduced from without, or, more probably, bred within the body. By degrees the patches both enlarge in size, and multiply in number, and extend along the extremities to the trunk. The eruption is seldom seen upon the hairy scalp, or upon the hands. As the patches enlarge they sometimes become confluent; but even then, the outline of the confluent scaly space is defined by arcs of circles, and the disorder is sufficiently distinguishable from *psoriasis*. It is not easy to set these things before you in mere verbal description. To have *seen* lepra once, is to know it for ever.

When the patches begin to get well, the restoration of the altered surface to its natural condition and appearance commences in the centre—*i. e.* in the spot first affected—and proceeds outwardly towards the circumference: so that the scaly redness assumes a ring-like arrangement. This ring becomes gradually narrower and narrower; at length its continuity is here and there broken; and at last it vanishes entirely.

The eruption does not, however, run any definite course. Sometimes it goes rapidly through its phases; in other cases it persists for a very long period. It is not at all contagious.

Neither is lepra attended, in general, with much local inconvenience, nor with much constitutional disturbance. When the eruption is very copious and extensive, and especially when it is plentiful or almost continuous around the larger joints, it renders the movements of the limbs stiff and difficult; and even sometimes painful, from the cracking of the inflamed surface as it is stretched in the bending of the joint.

But I have seldom found lepra to exist *unconnected* with some disorder of the digestive organs. Usually the connexion is that of alternation, and not of coexistence. The patient is dyspeptic till the eruption comes out, and then the dyspepsia is relieved: and it often returns as the leprous patches disappear. The eruption is the more unsightly; the dyspepsia is the more troublesome. This alternation would seem to mark the shifting location of the *matrices morbi*.

When the patches are small, and chronic, and white, that variety is no longer called lepra vulgaris, but lepra *alphoides*; and there certainly is another distinct variety, of a more blue, or livid, or copper colour than the ordinary; and a result of the poison of syphilis. It is named accordingly syphilitic lepra. This species will

get well under the influence of mercury; which, so far as my observations go, does not cure the others.

Psoriasis is closely allied to lepra. When it occurs in distinct patches it is often difficult to say to which genus the eruption belongs. In general the patches of psoriasis are not so broad as those of lepra; their edges are less raised, and their centres less depressed; the scales adhere more firmly; and the patches are less uniform and less circular.

But, psoriasis frequently spreads itself over large portions of the skin, and it may come to occupy nearly the whole surface of the body. It is then called psoriasis *diffusa*. It often renders the patient hideous to look at. The scaly incrustation is interspersed with chaps, furrowing the skin in all directions, and following particularly its natural folds and angles. These cracks, when the skin is put upon the stretch by the movements of the patient, are apt to bleed. In these severer cases (which are said to be examples of psoriasis *inveterata*) the laminae of altered cuticle are thick, and very abundant. They fall off perpetually, or are rubbed off, and may be shaken from the patient's clothes, or collected in handfuls from his bed.

Both these scaly disorders, lepra and psoriasis, require the same kind of treatment.

I believe that external applications are of but little use. I have tried a good many, and have lost all confidence in them, with the exception of the warm bath. Whatever tends to improve the general health, will hasten the departure of these eruptions. I believe that they sometimes depend upon the presence, or the generation, of an excess of acid in the system; and that they are often to be cured by alkaline remedies I am sure. I have seen many cases of psoriasis rapidly improve, and get ultimately well, under full doses of the *liquor potassæ*; from half a drachm to a drachm, three or four times daily, in a glass of milk, or of water, or of beer, or of ginger tea. Another internal remedy from which I have seen manifest improvement result, is arsenic; given with the cautions, and in the doses, which I have more than once spoken of. These are the two remedies of which I have the most experience; but neither of them is infallible; and you will have to try many things in succession, for patients are very desirous of getting rid of the disfiguring eruption, even when it does not interfere with their health or comfort. Now the Harrowgate waters, a strong decoction of dulcamara, pitch-pills (and if pitch-pills, I should suppose *à fortiori* creasote), tincture of cantharides, and the iodide of potassium, are remedies of some renown for these scaly diseases. Of the syphilitic lepra I repeat that mercury will prove a cure. In all cases the diet must be regulated, and all kinds of stimulating food abstained from. Dr. Bateman knew a man who was always attacked with lepra if he took spices with his food, or drank ardent spirits: and a patient of my own got rid of long-standing and very troublesome psoriasis of the scrotum, upon adopting, for other reasons, a very abstemious and simple mode of living.

Parts of the surface of the body—the chest, the neck, the shoulders, the abdomen, even the forehead—are marked sometimes by irregular brown patches of what is called *Pityriasis*; from *πυρρον*, bran. The discoloured portions are in fact covered with small bran-like films, which fall off, and are succeeded by others. I call your attention to one variety of pityriasis, the pityriasis *versicolor*, chiefly because it is (like the favus confertus or scald-head) a sample of the *vegetable parasites* with which the human integuments are liable to be defaced. Viewed through a microscope, these bran-like scales present the spores and filaments of a minute cryptogamous plant or fungus, the *microsporum furfurans*. Pityriasis is an eyesore or blemish rather than a disease: but it sometimes excites the apprehension of some syphilitic or other constitutional taint. Whether the skin upon which this fungus clings and grows must be in an unhealthy state to admit of its first invasion, has not been learned. Drugs are often diligently administered to cure the disfigurement: but I suspect that they are always useless and superfluous. Some years ago, before I was aware of the true character of these blotches, I tried various means, in vain, to remove a large one from the neck of a young lady whose beauty it was marring. At length it yielded at once to a couple of sulphur baths. The medication must be external. A saturated solution of sulphurous acid gas in water is an effectual remedy; or the parasitic plant may be killed and dislodged by a wash containing corrosive sublimate.

Among the *pustular* diseases of the skin there is one which assumes many forms,

and is termed *impetigo*. Whatever may be the minuter peculiarities of this eruption, its general characters are the following. It consists of crops of pustules, sometimes scattered irregularly, sometimes collected into groups. The pustules burst, or are broken, dry up, and scab over. The crusts are yellowish, and very friable, and resemble in appearance little masses of candied honey; or sometimes they look like small pieces of dirty plaster. From beneath these crusts a considerable discharge continues to take place; the crusts become thicker and larger, and around their margins the skin is red and raw, as it is also beneath them.

We have, I say, various forms of this complaint; *impetigo figurata*, *impetigo sparsa*, &c. It often borders closely on eczema, so that authors describe an eczema *impetiginodes*, or an *impetigo eczematodes*. These varieties are delineated by Rayer, by Willan and Bateman, and by others; and knowing their characters, you can examine and study their appearances for yourselves. Impetigo is a non-contagious disorder.

Sometimes this complaint occurs in an acute form, and is attended with fever. In such cases its removal will be accelerated by moderate bloodletting; and the blood drawn will be found to present the buffy coat. Whatever local applications are made should not be unctuous. It is seldom that impetigo will bear, or be the better for, ointments. Purgatives and alkalies internally, and very weak spirit or alkaline lotions externally, with a scrupulous diet, constitute, I believe, its best treatment. When the complaint is chronic, and the discharge copious, the oxide of zinc has often a very beneficial effect. It may be dusted over the affected surface, from a thin muslin bag; or it may be applied in the shape of a lotion—fifteen grains to an ounce of rose-water. You will find this a most useful lotion for that disfiguring impetiginous or eczematous eruption which sometimes covers the faces of children like a mask, and is called *crusta lactea*. The phrase *crusta lactea* is, however, very loosely employed by medical men.

There is a very common, and a very teasing pustular disease of the skin, usually called a *boil*, in some parts of England a *push*, and by the learned *furunculus*.

First, there is a slight degree and extent of hardness to be felt, a tender knot, just beneath the surface, which soon begins to look red, and a small swelling arises, which gradually increases up to a certain size, that of a large pea, or of a hazel-nut, or of a walnut. The tumour is painful, and undergoes a process of slow suppuration. Some time from the fourth to the eighth day it acquires a conical or pointed form, and its apex becomes of a white or yellow colour. At last the cuticle gives way, and the patient begins to congratulate himself that the little abscess is ripe, and that his troubles are nearly ended. But he is disappointed; an insignificant quantity of pus mixed with blood escapes, and leaves visible a mass of dead areolar tissue—a *core*, as it is called—of greater diameter than the opening, which is commonly small. At last, two or three days perhaps after this, the slough is expelled, in company with more pus, and a deep cup-like cavity remains, which soon, however, fills up, and the boil is really over.

These little phlegmons frequent the buttocks, the thighs, the arm-pits, the nape of the neck, the abdomen. They may occur almost anywhere. They are apt to come in crops, or in a series: and any kind of irritation suffices to cause them when a constitutional tendency to their formation exists. I have known a piece of soap plaster applied to the skin give occasion to a long succession of boils. Poultices, applied to promote the suppuration of any existing furunculus, are believed to encourage, by their warmth, the growth of others around it. In truth, these phlegmons belong primarily and essentially to the subcutaneous areolar tissue rather than to the skin. Dr. Prout corroborates the statement of Cheselden, that they are often accompanied by a saccharine condition of the urine. You know probably that, in Dr. Prout's theory of assimilation, the areolar tissue represents the saccharine element.

Boils have been very prevalent for some few years past in this country: and not here only, but on the continent of Europe also, and throughout America. It is stated—by an anonymous contributor to the *Medical Times* (December 2, 1854), who founds his conclusions upon the observation of several hundred cases among the out-patients of St. Bartholomew's Hospital, and of the Hospital for Skin Diseases—that the number of males affected with boils in a given time is rather more than double the number of females: also, generally, that boils are twice as common during the first four months, as during other parts of the year.

The individual boils are intractable: the state of system which engenders them, or

which favours their formation, may often, I believe, be corrected. Some dab them, when nascent, with a solution of corrosive sublimate in spirit; some support them with sticking-plaster; some paint them with the compound tincture of iodine; others apply poultices, or what is better, and perhaps the best local application, lint wetted with water and covered with oiled silk; and others again cut the hard tumour through, while it is yet crude. Do what you will, you can seldom prevent or accelerate their deliberate course; but I believe that by applying leeches, or cold, you may prolong, though you cannot arrest that course.

From the time of John Hunter, who cured himself of a disposition to boils by taking "the fossil caustic alkali, night and morning, in milk for two months," it has been the fashion to prescribe alkalies for persons so troubled; particularly the liquor potassæ, in combination with sarsaparilla: but I have satisfied myself that a better remedy—of opposite chemical quality—is to be found in the dilute sulphuric acid. For some three years, acting upon a hint received from Dr. Bullar, of Southampton, I have given this acid, twice daily, before meals, in doses of ten or fifteen minims, to a great number of persons who were infested with boils, and the instances have been very few in which it has failed to check the tendency to their formation. When the system is below par, the sulphate of quina, and a generous regimen, may be added: meanwhile sugar, and saccharine food of all kinds should be scrupulously avoided.

Carbuncle, *alias* anthrax, is a gigantic boil, and something more. It constitutes a far more serious disorder than the common furuncle, not only in respect of its magnitude, and of the amount of suffering which it occasions, but also on account of the constitutional vice that it betokens. A carbuncle is a large, flat, circumscribed, very hard, and very painful tumour, of a purplish red colour, and attended with a sensation of burning heat. Its ultimate diameter may be three or four inches or more. It ends in the formation of a deep slough, of more than corresponding dimensions, and the destruction of the skin above it. A number of pinhole openings at length present themselves on the dark red surface, and disclose the immense core beneath.

That carbuncles and boils are *kindred* disorders appears distinctly from this—that occasionally a carbuncle results from the confluence of two or three boils which had arisen near each other: and not less distinctly from the simultaneous prevalency of the two. The recent increase of the carbuncular disease has been even more marked than that of the furuncular. Of this I may offer you proof from the records of the Registrar-General. These records deal, indeed, with fatal instances only. Of course the whole number of cases that occurred in the same periods must have been far greater. In the five years ending with 1845, the average number of deaths from carbuncle in London alone was 5; in the next five years, ending with 1850, the number increased to 14: in 1851, it amounted to 19: in 1852, to 50: in 1853, to 70: and in 1854, to 89. In this year, which you will recollect was the cholera year, the deaths from carbuncle in England, exclusive of London, were no fewer than 300.

The cause of this vast increase of these disorders has not, I think, been ascertained. Professor Laycock indeed imputes it to their *contagious* properties—classing together boils, carbuncles, whitlow, and the charbon and pustule maligne of the French, which are less frequently seen in this country, under the common title of the *contagious furunculoid*. He suggests the question whether that disease may not have had an epizootic origin, and whether its present wider and wider diffusion may not be derived from the imported hair and hides of animals affected with a carbuncular distemper, which has been epidemic among cattle in the South of France, Italy, Germany, Poland, Hungary, and Russia. I am bound to tell you that, in my judgment, this alleged quality of contagiousness, with respect at least to the two forms of disease with which we are most familiar here, the boil and the carbuncle, is "not proven."

Carbuncle is met with chiefly in advanced life, in corpulent males, and in persons who have lived fully: chiefly, but not exclusively. The writer in the *Medical Times*, to whom I have already referred, gives a tabular account of 35 cases of carbuncle, of which 25 were noted, within six months, among the patients at St Bartholomew's Hospital. Instances of it occurred at various period of life from 15

years of age to 80; among the ill-fed and the well-fed, the temperate and the intemperate, and more than twice as often in males as in females. Though the carbuncles may appear in almost any place, they most commonly affect the more brawny portions of the skin, and the hinder parts of the body; the nape of the neck, the shoulders, the buttocks. I have however myself seen a large carbuncle on the belly. A virulent form, resembling the pustule maligne of the French, has been described as occurring upon the face, at St. Bartholomew's, by Dr. Harvey Ludlow. Carbuncle is then perhaps most dangerous, though not necessarily fatal, when it attacks the scalp.

The local disease is productive of high constitutional disturbance and irritation. Surgeons are in the habit of dividing the firm mass into quarters, by deep crucial incisions. This is a sharp remedy, but it purchases speedy ease, by removing that tension of the inflamed parts whereupon the pain chiefly depends. I am persuaded, however, that this severe operation has been done too indiscriminately. When there is no evident tension, when there is not much complaint of pain, and the inflammation is not extending, you had better, in my opinion, leave these tumours to the care of nature, and address your remedies to the system at large. Support is almost always needed; and opiates are sometimes indispensable; and the bowels must be kept clear by purgatives. When the interference of surgery is requisite, Mr. Travers, Junr., advocates the destruction of the central integuments by caustic, rather than their division crosswise by the knife; for this, among other reasons, that less hazard is so incurred of subsequent phlebitis.

I shall not attempt to discuss, even in this cursory and disjointed manner, any more of the inflammatory affections of the skin, whether acute or chronic: but I wish, before I conclude, to direct your attention to a peculiar morbid condition, of much greater consequence and interest than many of those which I have just been describing. I mean the malady which is best known by the appellation of *purpura*, or the purples, and which usually, though it must be confessed very incorrectly, is ranked among cutaneous disorders. It is strictly a hæmorrhage. Its external phenomena are so obvious, and so well known, that I need not dwell upon them. Small round spots appear on various parts of the surface, generally upon the legs first and most plentifully, of a dull crimson, or of a deep purple colour. They are accompanied by no local pain, by no sensation of any kind. Pressure upon them does not efface the colour, nor render it fainter, as it does that of inflammatory spots of the skin. There is scarcely ever any prominence of the purple stigmata; but they are sometimes intermixed with livid blotches, with appearances exactly resembling bruises: and both the circular spots and the ill-defined vibices undergo, before they disappear, the same changes of colour, from red or blue to a greenish yellow, which a bruise undergoes. In fact the anatomical condition of a bruise is exactly the same with the condition of the diffused livid blotches of purpura. In each case the colour is the result of ecchymosis. With all this, passive hæmorrhages from various parts, and particularly from the mucous membranes, are common.

It is clear, therefore, that this complaint cannot be regarded as a cutaneous complaint, even in the loose sense in which that epithet is sometimes applied to affections which are really *beneath* the skin, but visible *through* it. The hæmorrhage takes the form of red or purple spots when the quantity of blood extravasated in the same place is only a drop. And the spots are not peculiar to the skin, nor to the subcutaneous tissues, but are found, occasionally, upon all the internal surfaces also, and within the substance of the several viscera. I have seen these purple spots on the mucous surface of the mouth, the throat, the stomach, and the intestines, on the pleure and pericardium in the chest, on the peritoneal investment of the abdominal organs, in the substance of the muscles, and even upon the membranes of the brain, and in the sheaths of the larger nerves; and I have known them to be accompanied with large extravasations of blood in most of the vital organs of the body.

The superficial markings of purpura, the red and purple spots and livid blotches, exactly resemble the spots and bruise-like stains which characterize sea-scurvy: and I confess that I formerly regarded the two affections as being identical, or as mere varieties of the same disorder. But it is not so. For a very full and interesting account of scurvy, I must refer you to an essay, by Dr. Budd, in the *Library of Practical Medicine*. He has there collected from various sources, and exhibited in

a clear light, convincing evidence that scurvy is caused — neither by contagion, nor by cold weather, nor by impurity of the air, nor by the continued use of salt provisions, all of which have been alleged as sources of the disease, but — by the privation, for a considerable length of time, of fresh succulent vegetables. Now purpura often makes its appearance when there has been no deficiency of such food, and no remarkable abstinence from it. Scurvy is most common in winter, or in the beginning of spring; purpura in the fruit seasons, in summer and autumn. In scurvy the gums are uniformly soft, and swelled, and spongy, and bleed readily; this is no necessary feature in purpura. Scurvy is marked by extreme debility and dejection of spirits; it is always rendered worse by blood-letting and by mercury; and it is infallibly and rapidly cured by the administration of lemon-juice, or of other fresh fruits and vegetables. Purpura, on the other hand, often requires venæsection for its cure; it is not constantly nor surely, if ever, benefitted by the antiscorbutic juices; it is not always attended by sponginess of the gums, nor by feebleness of the mind and body; and I have seen it clear speedily away upon the supervention of mercurial salivation, and hypercatharsis.

Lemon-juice is really a specific against scurvy, whether it be employed as a preventive or as a remedy. It supplies something to the blood which is essential to its healthy properties. Its virtues were known in this country more than two hundred years ago, as appears from the work entitled *The Surgeon's Mate, or Military and Domestic Medicine*, by John Woodall, Master in Surgery: London, 1636. But the merit of making the fact generally known, and of procuring the systematic introduction of lemon-juice into nautical diet, by an order from the Admiralty, is due to Dr. Blair, and Sir Gilbert Blane, in their capacity of Commissioners of the Board for Sick and Wounded Seamen, in 1795. "The effect (says Sir John Herschel) of this wise measure may be estimated from the following facts. In 1780 the number of cases of scurvy received into Haslar Hospital was 1457: in 1806 *one* only, and in 1807 *one*." He adds, "there are now many surgeons in the navy who have never seen the disease."

Dr. Budd, however, has assured me that the Dreadnought Hospital-ship, at Greenwich, is often full of cases of scurvy; most of the patients so affected having just arrived in *merchant-ships*, from a long voyage. This surely ought not to be. It *could* not be if the owners of these vessels knew how easily, surely, and cheaply, this truly dreadful scourge may be averted.

Scarcely less — if indeed less at all — of antiscorbutic virtue, belongs, fortunately, to that common esculent root, the potatoe. *Raw* potatoes have long been in good repute, both for the cure and for the prevention of scurvy: but raw potatoes are neither palatable, nor easy of digestion; and it is a great discovery, which we owe to the sagacity of Dr. William Baly, that this vegetable is equally effective for these purposes, when cooked. During some months of continued observation of the prisoners confined in the Penitentiary at Millbank, I had remarked, without being able to account for it, that among the small number of *soldiers*, committed for comparatively short periods, for offences against military discipline, scurvy was not uncommon; whereas I noticed it in one instance only among the much more numerous class of *convicts*, whose term of imprisonment was considerably longer. Dr. Baly was afterwards appointed Physician to the Penitentiary, and the same curious fact soon caught his attention: and he has traced the cause. By the examination and comparison of various dietaries — those, namely, which have been adopted at different periods in the Penitentiary itself, those which, at the same period, were prescribed respectively for the military offenders, and for the ordinary convicts, and those in use in sundry other jails in which scurvy has occurred with different degrees of frequency — he has shown, most satisfactorily, that the liability to that malady has a strict relation to the amount of succulent vegetables consumed by the prisoners, and especially of potatoes. "Wherever this disease has prevailed, there the diet of the prisoners, though often abundant in other respects, has contained no potatoes, or only a very small quantity. In several prisons, the occurrence of scurvy has wholly ceased on the addition of a few pounds of potatoes being made to the weekly dietary. There are many prisons in which the diet, from its unvaried character, and the absence of animal food, as well as green vegetables, is apparently most inadequate to the main-

tenance of health ; and where nevertheless, from its containing abundance of potatoes, scurvy is not produced."

In corroboration of these views may now be adduced the remarkable prevalence of scorbutic complaints in these islands, subsequently to the potatoe rot of 1846.

Now potatoes are *food* as well as medicine, and they are a cheap kind of food, and it may be hoped that a more general knowledge of their antiscorbutic properties, even when cooked, will abolish this wretched complaint, whenever a good supply of them is attainable. Dr. Baly believes that from three to six pounds, weekly, for each person, would suffice. He thus accounts for their salutary influence.

"A glance at the chemical analysis of the potatoe at once explains its antiscorbutic virtue. The various fruits, succulent roots, and herbs, which have the property of preventing and curing scurvy, all contain, dissolved in their juices, one or more organic acids — such as the citric, tartaric, and malic acids. Sometimes these acids exist in the free state, but more generally they are combined with potass, or lime, or with both these bases. Now potatoes have been submitted to most elaborate chemical examination by Einhoff and Vauquelin ; and by both these chemists they have been found to contain a vegetable acid in considerable quantity. According to Einhoff, this acid is the tartaric combined with potass and lime. According to Vauquelin it is the citric, partly in combination with those bases, and partly in the free state. The farinaceous seeds, as wheat, barley, oats, and rye, which are destitute of antiscorbutic property, contain no organic or vegetable acids."

My friend Dr. Martin, of Ventnor, believes that the *cruciferae*, and water-cress especially, have more speedy and sure effect in removing sea-scurvy, than even lemon-juice. He assures me that, at St. Helena, he has seen the worst forms of the disease cured in the space of three days by an abundant ingestion of water-cresses.

Quite recently, (1848,) Dr. Garrod has re-investigated this subject, both chemically and clinically, and finds reason to distrust the "acid" theory, so long and so generally received. The disorder being clearly attributable to the *absence* of some essential ingredient in the food, and not to the *presence* of any noxious substance, he believes, and brings forward strong grounds for his belief, that *potass* is the deficient ingredient. If this be so, it is a most important discovery.

According to Dr. Garrod, the acids themselves, when separated from the antiscorbutic fruits and vegetables,—the citric and the acetic acids for example,—manifest no antiscorbutic virtues.

The following propositions form the substance of his very interesting announcement.

"1. That in all scorbutic diets, *potass* exists in much smaller quantities than in those which are capable of maintaining health.

"2. That all substances proved to act as antiscorbutics contain a large amount of *potass*.

"3. That in scurvy the blood is deficient in *potass*, and the amount of that substance thrown out by the kidneys is less than that which occurs in health.

"4. That scorbutic patients will recover when *potass* is added to their food, the other constituents remaining as before both in quantity and quality, and without the use of succulent vegetables, or of milk.

"5. That the theory which ascribes the cause of scurvy to a deficiency of *potass* in the food, is also capable of rationally explaining many symptoms of that disease."

The last of these propositions requires a little further unfolding. "Both soda and potass are constant constituents of the animal body, and it appears that they are not capable of replacing each other. For example, we always find the potass to exist in large quantities in the ash of muscle, soda in very small quantities. (Berzelius, Liebig). In the ash of the blood we find the relation reversed. It appears also that the muscular system requires the presence of potass ; and we should therefore expect to find that where there is a deficient supply of this base, the effect would soon be manifested in the functions of that system. This we find to be the case in scurvy. Without any amount of wasting of the body we find marked muscular debility ; and this perhaps is one of the earliest symptoms of the disease."

I say, if this theory of Dr. Garrod's prove true, its importance is great and manifest. Scurvy, whether on land or at sea, may henceforward be cured, or prevented, by a remedy at once simpler, cheaper, more easily portable, and more imperishable even than lemon-juice. At all times, and in every place, it may be procured from

the ashes of wood, or of plants,—especially (as Dr. Garrod has suggested) from that ubiquitous weed, tobacco, which contains it in abundance. A few grains of some salt of potass, — the neutral tartrate, for instance, the chlorate, or the phosphate, — might be mixed with the daily food, or administered as physic. Dr. Garrod concludes his paper by remarking, that even should his anticipation of the sanative quality of this substance be disappointed, it will still remain an interesting matter of fact, “that *potass* always accompanies the *real* antiscorbutic principle, was found deficient in scorbutic blood, and that several cases of scurvy rapidly recovered under the use of some of its salts, without the administration of any other remedy, dietetical or medicinal.”

The same causes which give rise to *sea* scurvy will produce precisely the same effect on land. Of this I must give you one illustration from my own case-book. In August, 1830, I admitted into the Middlesex Hospital a blacksmith, thirty-five years old, covered with round purple spots of various sizes, and with irregular blotches of ecchymosis. He had *vomited* blood on the preceding day. He was continually *coughing up* blood at the time of his admission, and his wife estimated the whole quantity that he had then lost to be more than half a pailful. The interior of his mouth and palate was pouring forth blood from a number of livid fungous tumours, formed by the extravasation of blood into the areolar tissue beneath the membrane, and the subsequent rupture of that membrane. He was passing blood by the *bowels* also; and his *urine* was loaded with blood.

Here were the *symptoms* of scurvy strongly marked. In the man's history we could trace its peculiar *cause*. He had long been subsisting on very poor and insufficient nutriment, seldom eating any meat, but living almost entirely on tea, coffee, and bread and butter. He had been too ill and weak to work regularly, yet he had been obliged occasionally to over-exert himself to obtain a scanty supply of food for himself, his wife, and a large family of children. He had been a settled dram-drinker, but for some time had taken much less of that stimulus; merely because he had not the means of procuring it. His pulse was frequent and feeble.

I had not much hope that this patient could be saved by any treatment. He was immediately put upon a diet of roast meat, and began to take daily half a pint of fresh lemon-juice diluted with a pint and half of water. This plan, with some tonic medicine, was commenced on the 3d of August. He improved at once. On the 8th all hæmorrhage had ceased; the fungous tumours in the mouth had disappeared, leaving small scars in the places they had occupied; and the discolouration of the skin was almost gone. The amendment was so striking and rapid, and so immediately consequent upon the institution of the treatment, that no room was left for mistaking recovery for cure.

It is chiefly by investigating the previous history of the patient, and by noting the degree of strength that he possesses, and the condition of his pulse, that we are guided in our diagnosis of ambiguous cases. The late Dr. Parry, of Bath, was one of the first to point out the efficacy of abstinence, venæsection, and purgatives, in some instances, at least, of purpura. I may refer you to an example of this kind detailed in the *Medical Gazette* for the 5th of April, 1828. It occurred in one of Dr. Latham's hospital patients; and several of the symptoms were very like those I have just been relating. In particular the whole tongue was livid, one half of it presenting the appearance of a large, black, bleeding fungus; and on the inner surface of each cheek were several black fungoid patches. The patient was voiding also unmixed blood from the bowels. In this case there was no evidence of the operation of any debilitating cause, and the pulse, though frequent, was *hard*. Bleeding from the arm always gave relief to his uneasy sensations: he was purged also, and put upon low diet. Under this plan he steadily improved, and in four or five days no vestige of the complaint remained except the fading spots. For some time afterwards, however, “the frequent use of active purgatives, and a rigid restriction to low diet, were necessary to obviate costiveness, and to keep down the circulation, which had a tendency to become over-active.”

You are not to suppose that all cases of purpura bear this sthenic character, or require these heroic remedies. Your treatment must be guided by the previous circumstances and habits of the patient, by the state of his pulse, and by the other symp-

toms which accompany the purple spots. And when you are in doubt what plan to pursue, make a cautious tentative bleeding. Take away a couple of ounces at a time, into a wine-glass, note carefully the appearance of the blood itself, and the effect of the bloodletting upon the patient; and then go on more boldly, or abstain thenceforth altogether from the lancet, according to circumstances. In many cases your chief reliance will be placed in the watchful employment of purgatives. These have been highly recommended by Dr. Harty, of Dublin, as having proved eminently successful in his practice. The late Dr. Whitlock Nicholl, and others, have spoken in terms of strong praise of the oil of turpentine, administered in moderate and repeated doses, as a remedy in purpura.

I have adverted to one peculiar source of danger in purpura, the hazard that blood may be effused in some vital organ where even a slight amount of hæmorrhage suffices to extinguish life. Dr. Bateman states that he had seen three instances in which persons were carried off, while affected with purpura, by hæmorrhage into the lungs. During the course of one week, in the year 1825, I was present at two inspections in the dead house of St. Bartholomew's Hospital, illustrative of the same point in respect of another vital organ, and involving a question in forensic medicine. The subjects of examination were both of them women of middle age who had been brought into the hospital covered with purple spots and bruise-like discolourations, and suffering hæmorrhage from the mucous membranes. Each of these women declared that the apparent bruises were marks of beatings received from her husband. One of them became suddenly hemiplegic a little while before she died. Of the manner of dissolution in the other case I am not sure. In both instances a considerable quantity of blood was spread over the surface of the brain, between its membranes: and in one of them, blood had been shed also into the cerebral substance, which it had extensively lacerated.

It may be worth mentioning that in one of these corpses there were indications, either of unusually rapid putrefaction after death, or (what I think more probable) of some degree of decomposition even before life was extinct. This woman died in the evening, and the body was examined the next day, twelve or fourteen hours afterwards. A quantity of fætid gas escaped from the cavity of the abdomen as soon as it was opened, and small bubbles of air were seen to ooze from the areolar tissue of various parts of the body. Even when incisions were made into the *liver*, air frothed up, as it might do, under ordinary circumstances, from a section of the lungs.

I have no time left for discussing the pathology of these complaints. They are eminently *blood-diseases*. In scurvy the blood is starved of some essential ingredient, (probably potass,) which the juice of lemons, or other fresh succulent vegetable food, readily supplies and renews. When drawn from a vein the blood is often visibly unnatural. A very small quantity was taken before I saw him, from the arm of the blacksmith whose case I just now mentioned. After standing for some time, it continued to fill the whole area of the vessel in which it had been received, without any apparent contraction, or separation of serum. On its flat upper surface was a thick, gray, semitransparent jelly, and beneath this there was, strictly speaking, no coagulum, but a black, semi-fluid substance of the consistence of syrup. Huxham describes similar appearances. "The blood of such persons (says he), when it hath been drawn off, always appears a mere gore, as it were, not separating into crassamentum and serum as usual, but remaining in a uniform half coagulated mass, generally of a livid or darker colour than usual, though sometimes it continues long very florid; but it always putrefies very soon." In another place, when describing a particular case, he says, "I found that neither of the portions of the blood that had been drawn had separated into serum and crassamentum as usual, though it had stood many hours; but continued, as it were, half coagulated, and of a bluish livid colour on the top. It was most easily divided on the slightest touch, and seemed a purulent sanies rather than blood, with a kind of sooty powder at bottom."

Dr. Budd, however, states that in some cases of scurvy the separation of blood into serum and clot is as perfect, and takes place as readily, as in healthy blood.

When you recognize the disease as genuine scurvy, and trace a previous abstinence, whether forced or voluntary, from fresh vegetables, the treatment is plain; you must

supply the kind of nutriment which has been defective, and support your patient's strength in such other ways as the circumstances of the case may dictate.

And now, gentlemen, I must needs stop. Here ends my course. And if this were all I had to say, I should say it with something like glee, and you, no less than myself, would rejoice that at length a breathing-space and holiday had arrived. But I cannot feel so when I add that this is the last lecture, not of this course merely, but the last of any kind, that I am ever likely to deliver in King's College. I cannot say this without concern and regret.

I am quite aware that my lectures have been in many respects imperfect. They have been very unequal to my own wishes. But they have been as full, and as carefully weighed, as my broken leisure, and irregular opportunities, and slender ability, would permit. I can only hope that at any rate I have not misled you. If I have been intelligible, if I have drawn such a sketch of a great and difficult subject as may help you in studying it for yourselves, I have achieved my task. I told you, in the outset, that I could not here teach you the *practice* of physic, but only its *principles*. It would be idle for me to speculate further upon the success of my endeavours. You are to be the judges of that matter. Whatever rules and precepts I have laid down, you will soon test by your own experience, and adopt or reject them accordingly. The well-known maxims of Bacon apply with especial truth to medical instructors and their pupils. "*Etsi non displiceat regula, oportet discipulum credere; huic tamen coniungendum est, oportet jam edoctum iudicio suo uti: discipuli enim debent magistris temporariam solum fidem, iudicique suspensionem, donec penitus imbibierint artes: non autem plenam libertatis ejurationem, perpetuamque ingenii servitutem.*"

Retiring reluctantly from this place, in obedience to the force of circumstances, there are yet many things to comfort and console me. It is a great satisfaction to reflect that I have never had any serious disagreement with yourselves; have never experienced any but the most respectful and kind reception, either from my present or from any preceding class. I have reason to thank you—and I do thank you—for the courtesy and attention you have at all times shown me. It is a source of gratification also that I carry with me the good will, as I believe, of my excellent colleagues; and that I go without having forfeited any of that confidence which the Council first reposed in me as their servant, when they offered me, without solicitation, the chair I now resign.

Had I been a few years younger, unembarrassed by previous official engagements, and somewhat more at leisure than I am, I should have been glad and proud to have attached myself to the new hospital, and to have laboured still in the cause of King's College, and of its Medical School. But it is otherwise ordered: and I will mention as the last source of consolation in taking leave of you, my conviction that to you my loss (if without presumption I may so venture to speak of my resignation) will be more than supplied by my successor. I know that gentleman well. I know, indeed the world knows, his talents. He was highly distinguished in the Senate House at Cambridge. He has since devoted, and will continue to devote, the powers of a very strong intellect, to the investigation of disease. Dr. Budd is one of the most strenuous cultivators of our science that I am acquainted with: and I am confident—without any affectation of modesty—that he will soon give a much better course of lectures than you have heard from me. That you may prosper under his instruction, and afterwards; that by the humane exercise of our noble calling, you may do good in your generation, to others, and so to yourselves; is my earnest desire and prayer. I hope it is unnecessary for me to assure you that I shall always continue to take a lively interest in your welfare individually; and that it will give me sincere pleasure if I shall find any future opportunity of rendering you any service. Gentlemen, I do not like this sort of parting, and I will not further protract the pain that belongs to it; but bid you finally, and most cordially—Farewell.

I N D E X.

BLANCHARD & LEA'S MEDICAL AND SURGICAL PUBLICATIONS.

TO THE MEDICAL PROFESSION.

The prices on the present catalogue are those at which our books can generally be furnished by booksellers throughout the United States, who can readily procure any which they may not have on hand. To physicians who have not convenient access to bookstores, we will, as long as the existing rates of postage remain unchanged, forward them at these prices, *free* by mail, to any post-office in the United States under 1,500 miles. As we open accounts only with booksellers, the amount must in every case, without exception, accompany the order, and we assume no risks of the mail, either on the money or on the books; and as we deal only in our own publications, we can supply no others. Gentlemen desirous of purchasing will, therefore, find it more advantageous to deal with the nearest booksellers whenever practicable.

BLANCHARD & LEA.

PHILADELPHIA, October, 1862.

* * We have now ready a new edition of our ILLUSTRATED CATALOGUE of Medical and Scientific Publications, forming an octavo pamphlet of 80 large pages, containing specimens of illustrations, notices of the medical press, &c. &c. It has been prepared without regard to expense, and will be found one of the handsomest specimens of typographical execution as yet presented in this country. Copies will be sent to any address, by mail, free of postage, on receipt of nine cents in stamps.

Catalogues of our numerous publications in miscellaneous and educational literature forwarded on application.

☞ The attention of physicians is especially solicited to the following important new works and new editions, just issued or nearly ready:—

Ashton on the Rectum,	See page	3
Bumstead on Venereal,	"	5
Barclay on Medical Diagnosis,	"	5
Barwell on the Joints,	"	6

TWO MEDICAL PERIODICALS, FREE OF POSTAGE,

Containing over Fifteen Hundred large octavo pages,
FOR FIVE DOLLARS PER ANNUM.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, subject to postage, when not paid for in advance, \$5 00
THE MEDICAL NEWS AND LIBRARY, invariably in advance, 1 00
OR, BOTH PERIODICALS mailed, FREE OF POSTAGE (as long as the existing rates are maintained), to any post-office in the United States, for Five Dollars remitted in advance.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES,

EDITED BY ISAAC HAYS, M. D.,

is published Quarterly, on the first of January, April, July, and October. Each number contains at least two hundred and eighty large octavo pages, handsomely and appropriately illustrated,

wherever necessary. It has now been issued regularly for more than FORTY years, and it has been under the control of the present editor for more than a quarter of a century. Throughout this long period, it has maintained its position in the highest rank of medical periodicals both at home and abroad, and has received the cordial support of the entire profession in this country. Its list of Collaborators will be found to contain a large number of the most distinguished names of the profession in every section of the United States, rendering the department devoted to

ORIGINAL COMMUNICATIONS

full of varied and important matter, of great interest to all practitioners.

As the aim of the Journal, however, is to combine the advantages presented by all the different varieties of periodicals, in its

REVIEW DEPARTMENT

will be found extended and impartial reviews of all important new works, presenting subjects of novelty and interest, together with very numerous

BIBLIOGRAPHICAL NOTICES,

including nearly all the medical publications of the day, both in this country and Great Britain, with a choice selection of the more important continental works. This is followed by the

QUARTERLY SUMMARY,

being a very full and complete abstract, methodically arranged, of the

IMPROVEMENTS AND DISCOVERIES IN THE MEDICAL SCIENCES.

This department of the Journal, so important to the practising physician, is the object of especial care on the part of the editor. It is classified and arranged under different heads, thus facilitating the researches of the reader in pursuit of particular subjects, and will be found to present a very full and accurate digest of all observations, discoveries, and inventions recorded in every branch of medical science. The very extensive arrangements of the publishers are such as to afford to the editor complete materials for this purpose, as he not only regularly receives

ALL THE AMERICAN MEDICAL AND SCIENTIFIC PERIODICALS,

but also twenty or thirty of the more important Journals issued in Great Britain and on the Continent, thus enabling him to present in a convenient compass a thorough and complete abstract of everything interesting or important to the physician occurring in any part of the civilized world.

To their old subscribers, many of whom have been on their list for twenty or thirty years, the publishers feel that no promises for the future are necessary; but those who may desire for the first time to subscribe, can rest assured that no exertion will be spared to maintain the Journal in the high position which it has occupied for so long a period.

By reference to the terms it will be seen that, in addition to this large amount of valuable and practical information on every branch of medical science, the subscriber, by paying in advance, becomes entitled, without further charge, to

THE MEDICAL NEWS AND LIBRARY,

a monthly periodical of thirty-two large octavo pages. Its "NEWS DEPARTMENT" presents the current information of the day, while the "LIBRARY DEPARTMENT" is devoted to presenting standard works on various branches of medicine. Within a few years, subscribers have thus received, without expense, many works of the highest character and practical value, such as "Watson's Practice," "Todd and Bowman's Physiology," "Malgaigne's Surgery," "West on Children," "West on Females, Part I.," "Habershon on the Alimentary Canal," &c.

While the work at present appearing in its columns is

CLINICAL LECTURES ON THE DISEASES OF WOMEN.

By PROFESSOR J. Y. SIMPSON, of Edinburgh.

WITH NUMEROUS HANDSOME ILLUSTRATIONS.

These Lectures, published in England under the supervision of the Author, carry with them all the weight of his wide experience and distinguished reputation. Their eminently practical nature, and the importance of the subject treated, cannot fail to render them in the highest degree satisfactory to subscribers, who can thus secure them without cost. These Lectures are continued in the "News" for 1862.

It will thus be seen that for the small sum of FIVE DOLLARS, paid in advance, the subscriber will obtain a Quarterly and a Monthly periodical,

EMBRACING NEARLY SIXTEEN HUNDRED LARGE OCTAVO PAGES,

Those subscribers who do not pay in advance will bear in mind that their subscription of Five Dollars will entitle them to the Journal only, without the News, and that they will be at the expense of their own postage on the receipt of each number. The advantage of a remittance when ordering the Journal will thus be apparent.

Remittances of subscriptions can be mailed at our risk, when a certificate is taken from the Postmaster that the money is duly inclosed and forwarded.

Address **BLANCHARD & LEA, PHILADELPHIA.**

ASHTON (T. J.),

Surgeon to the Blenheim Dispensary, &c.

ON THE DISEASES, INJURIES, AND MALFORMATIONS OF THE RECTUM AND ANUS; with remarks on Habitual Constipation. From the third and enlarged London edition. With handsome illustrations. In one very beautifully printed octavo volume, of about 300 pages. (*Just Issued.*) \$2 00.

The most complete one we possess on the subject. *Medico-Chirurgical Review.*

We are satisfied, after a careful examination of the volume, and a comparison of its contents with those of its leading predecessors and contemporaries, that the best way for the reader to avail himself of

the excellent advice given in the concluding paragraph above, would be to provide himself with a copy of the book from which it has been taken, and diligently to con its instructive pages. They may secure to him many a triumph and fervent blessing.—*Am. Journal Med. Sciences.*

ALLEN (J. M.), M. D.,

Professor of Anatomy in the Pennsylvania Medical College, &c.

THE PRACTICAL ANATOMIST; or, The Student's Guide in the Dissecting-Room. With 266 illustrations. In one handsome royal 12mo. volume, of over 600 pages, leather. \$2 25.

We believe it to be one of the most useful works upon the subject ever written. It is handsomely illustrated, well printed, and will be found of convenient size for use in the dissecting-room.—*Med. Examiner.*

However valuable may be the "Dissector's Guides" which we, of late, have had occasion to

notice, we feel confident that the work of Dr. Allen is superior to any of them. We believe with the author, that none is so fully illustrated as this, and the arrangement of the work is such as to facilitate the labors of the student. We most cordially recommend it to their attention.—*Western Lancet.*

ANATOMICAL ATLAS.

By Professors H. H. SMITH and W. E. HORNER of the University of Pennsylvania. 1 vol. 8vo., extra cloth, with nearly 650 illustrations.  See SMITH, p. 331

ABEL (F. A.), F. C. S. AND C. L. BLOXAM.

HANDBOOK OF CHEMISTRY, Theoretical, Practical, and Technical; with a Recommendatory Preface by Dr. Hofmann. In one large octavo volume, extra cloth, of 662 pages, with illustrations. \$3 25.

ASHWELL (SAMUEL), M. D.,

Obstetric Physician and Lecturer to Guy's Hospital, London.

A PRACTICAL TREATISE ON THE DISEASES PECULIAR TO WOMEN.

Illustrated by Cases derived from Hospital and Private Practice. Third American, from the Third and revised London edition. In one octavo volume, extra cloth, of 528 pages. \$3 00.

The most useful practical work on the subject in the English language.—*Boston Med. and Surg. Journal.*

The most able, and certainly the most standard and practical, work on female diseases that we have yet seen.—*Medico-Chirurgical Review.*

ARNOTT (NEILL), M. D.

ELEMENTS OF PHYSICS; or Natural Philosophy, General and Medical.

Written for universal use, in plain or non-technical language. A new edition, by ISAAC HAYS, M. D. Complete in one octavo volume, leather, of 454 pages, with about two hundred illustrations. \$2 50.

BIRD (GOLDING), A. M., M. D., &c.

URINARY DEPOSITS: THEIR DIAGNOSIS, PATHOLOGY, AND

THERAPEUTICAL INDICATIONS. Edited by EDMUND LLOYD BIRKETT, M. D. A new American, from the fifth and enlarged London edition. With eighty illustrations on wood. In one handsome octavo volume, of about 400 pages, extra cloth. \$2 00. (*Just Issued.*)

The death of Dr. Bird has rendered it necessary to entrust the revision of the present edition to other hands, and in his performance of the duty thus devolving on him, Dr. Birkett has sedulously endeavored to carry out the author's plan by introducing such new matter and modifications of the text as the progress of science has called for. Notwithstanding the utmost care to keep the work within a reasonable compass, these additions have resulted in a considerable enlargement. It is, therefore, hoped that it will be found fully up to the present condition of the subject, and that the reputation of the volume as a clear, complete, and compendious manual, will be fully maintained.

BENNETT (J. HUGHES), M. D., F. R. S. E.,

Professor of Clinical Medicine in the University of Edinburgh, &c.

THE PATHOLOGY AND TREATMENT OF PULMONARY TUBERCULOSIS, and on the Local Medication of Pharyngeal and Laryngeal Diseases frequently mistaken for or associated with, Phthisis. One vol. 8vo., extra cloth, with wood-cuts. pp. 130. \$1 25.

BARLOW (GEORGE H.), M. D.

Physician to Guy's Hospital, London, &c.

A MANUAL OF THE PRACTICE OF MEDICINE. With Additions by D. F. CONDIE, M. D., author of "A Practical Treatise on Diseases of Children," &c. In one handsome octavo volume, leather, of over 600 pages. \$2 75.

We recommend Dr. Barlow's Manual in the warmest manner as a most valuable *va-de-mecum*. We have had frequent occasion to consult it, and have

found it clear, concise, practical, and sound.—*Boston Med. and Surg. Journal.*

BUDD (GEORGE), M. D., F. R. S.,
Professor of Medicine in King's College, London.

ON DISEASES OF THE LIVER. Third American, from the third and enlarged London edition. In one very handsome octavo volume, extra cloth, with four beautifully colored plates, and numerous wood-cuts. pp. 500. \$3 00.

Has fairly established for itself a place among the classical medical literature of England.—*British and Foreign Medico-Chir. Review.*

Dr. Budd's Treatise on Diseases of the Liver is now a standard work in Medical literature, and during the intervals which have elapsed between the successive editions, the author has incorporated into the text the most striking novelties which have characterized the recent progress of hepatic physiology and pathology; so that although the size of the book

is not perceptibly changed, the history of liver diseases is made more complete, and is kept upon a level with the progress of modern science. It is the best work on Diseases of the Liver in any language.—*London Med. Times and Gazette.*

This work, now the standard book of reference on the diseases of which it treats, has been carefully revised, and many new illustrations of the views of the learned author added in the present edition.—*Dublin Quarterly Journal.*

BY THE SAME AUTHOR.

ON THE ORGANIC DISEASES AND FUNCTIONAL DISORDERS OF THE STOMACH. In one neat octavo volume, extra cloth. \$1 50.

BUCKNILL (J. C.), M. D., AND **DANIEL H. TUKE, M. D.,**
Medical Superintendent of the Devon Lunatic Asylum. Visiting Medical Officer to the York Retreat.

A MANUAL OF PSYCHOLOGICAL MEDICINE; containing the History, Nosology, Description, Statistics, Diagnosis, Pathology, and Treatment of INSANITY. With a Plate. In one handsome octavo volume, of 536 pages. \$3 00.

The increase of mental disease in its various forms, and the difficult questions to which it is constantly giving rise, render the subject one of daily enhanced interest, requiring on the part of the physician a constantly greater familiarity with this, the most perplexing branch of his profession. At the same time there has been for some years no work accessible in this country, presenting the results of recent investigations in the Diagnosis and Prognosis of Insanity, and the greatly improved methods of treatment which have done so much in alleviating the condition or restoring the health of the insane. To fill this vacancy the publishers present this volume, assured that the distinguished reputation and experience of the authors will entitle it at once to the confidence of both student and practitioner. Its scope may be gathered from the declaration of the authors that "their aim has been to supply a text book which may serve as a guide in the acquisition of such knowledge, sufficiently elementary to be adapted to the wants of the student, and sufficiently modern in its views and explicit in its teaching to suffice for the demands of the practitioner."

BENNETT (HENRY), M. D.

A PRACTICAL TREATISE ON INFLAMMATION OF THE UTERUS, ITS CERVIX AND APPENDAGES, and on its connection with Uterine Disease. To which is added, a Review of the present state of Uterine Pathology. Fifth American, from the third English edition. In one octavo volume, of about 500 pages, extra cloth. \$2 00.

BROWN (ISAAC BAKER),

Surgeon-Accoucheur to St. Mary's Hospital, &c.

ON SOME DISEASES OF WOMEN ADMITTING OF SURGICAL TREATMENT. With handsome illustrations. One vol. 8vo., extra cloth, pp. 276. \$1 60.

Mr. Brown has earned for himself a high reputation in the operative treatment of sundry diseases and injuries to which females are peculiarly subject. We can truly say of his work that it is an important addition to obstetrical literature. The operative suggestions and contrivances which Mr. Brown describes, exhibit much practical sagacity and skill,

and merit the careful attention of every surgeon-accoucheur.—*Association Journal.*

We have no hesitation in recommending this book to the careful attention of all surgeons who make female complaints a part of their study and practice.—*Dublin Quarterly Journal.*

BOWMAN (JOHN E.), M. D.

PRACTICAL HANDBOOK OF MEDICAL CHEMISTRY. Second American, from the third and revised English Edition. In one neat volume, royal 12mo., extra cloth, with numerous illustrations. pp. 288. \$1 25.

BY THE SAME AUTHOR.

INTRODUCTION TO PRACTICAL CHEMISTRY, INCLUDING ANALYSIS. Second American, from the second and revised London edition. With numerous illustrations. In one neat vol., royal 12mo., extra cloth. pp. 350. \$1 25.

BEALE ON THE LAWS OF HEALTH IN RELATION TO MIND AND BODY. A Series of Letters from an old Practitioner to a Patient. In one volume, royal 12mo., extra cloth. pp. 296. 80 cents.

BUSHNAN'S PHYSIOLOGY OF ANIMAL AND VEGETABLE LIFE; a Popular Treatise on the Functions and Phenomena of Organic Life. In one handsome royal 12mo. volume, extra cloth, with over 100 illustrations. pp. 234. 80 cents.

BUCKLER ON THE ETIOLOGY, PATHOLOGY, AND TREATMENT OF FIBRO-BRONCHITIS AND RHEUMATIC PNEUMONIA. In one 8vo. volume, extra cloth. pp. 150. \$1 25.

BLOOD AND URINE (MANUALS ON). BY JOHN WILLIAM GRIFFITH, G. OWEN REESE, AND ALFRED MARKWICK. One thick volume, royal 12mo., extra cloth, with plates. pp. 460. \$1 25.

BRODIE'S CLINICAL LECTURES ON SURGERY. 1 vol. 8vo. cloth. 350 pp. \$1 25.

BUMSTEAD (FREEMAN J.) M. D.,

Lecturer on Venereal Diseases at the College of Physicians and Surgeons, New York, &c.

THE PATHOLOGY AND TREATMENT OF VENEREAL DISEASES, including the results of recent investigations upon the subject. With illustrations on wood. In one very handsome octavo volume, of nearly 700 pages, extra cloth; \$3 75. (*Now Ready.*)

By far the most valuable contribution to this particular branch of practice that has seen the light within the last score of years. His clear and accurate descriptions of the various forms of venereal disease, and especially the methods of treatment he proposes, are worthy of the highest encomium. In these respects it is better adapted for the assistance of the every-day practitioner than any other with which we are acquainted. In variety of methods proposed, in minuteness of direction, guided by careful discrimination of varying forms and complications, we write down the book as unsurpassed. It is a work which should be in the possession of every practitioner.—*Chicago Med. Journal*, Nov. 1861.

The foregoing admirable volume comes to us, embracing the whole subject of syphilology, resolving many a doubt, correcting and confirming many an entertained opinion, and in our estimation the best, completest, fullest monograph on this subject in our language. As far as the author's labors themselves are concerned, we feel it a duty to say that he has not only exhausted his subject, but he has presented to us, without the slightest hyperbole, the best digested treatise on these diseases in our language. He has carried its literature down to the present moment, and has achieved his task in a manner which cannot but redound to his credit.—*British American Journal*, Oct. 1861.

We believe this treatise will come to be regarded as high authority in this branch of medical practice, and we cordially commend it to the favorable notice of our brethren in the profession. For our own part, we candidly confess that we have received many new ideas from its perusal, as well as modified many views which we have long, and, as we now think, erroneously entertained on the subject of syphilis.

To sum up all in a few words, this book is one which no practising physician or medical student can very well afford to do without.—*American Med. Times*, Nov. 2, 1861.

The whole work presents a complete history of venereal diseases, comprising much interesting and valuable material that has been spread through medical journals within the last twenty years—the period of many experiments and investigations on the subject—the whole carefully digested by the aid of the author's extensive personal experience, and offered to the profession in an admirable form. Its completeness is secured by good plates, which are especially full in the anatomy of the genital organs. We have examined it with great satisfaction, and congratulate the medical profession in America on the nationality of a work that may fairly be called original.—*Berkshire Med. Journal*, Dec. 1861.

One thing, however, we are impelled to say, that we have met with no other book on syphilis, in the English language, which gave so full, clear, and impartial views of the important subjects on which it treats. We cannot, however, refrain from expressing our satisfaction with the full and perspicuous manner in which the subject has been presented, and the careful attention to minute details, so useful—not to say indispensable—in a practical treatise. In conclusion, if we may be pardoned the use of a phrase now become stereotyped, but which we here employ in all seriousness and sincerity, we do not hesitate to express the opinion that Dr. Bumstead's Treatise on Venereal Diseases is a "work without which no medical library will hereafter be considered complete."—*Boston Med. and Surg. Journal*, Sept. 5, 1861.

BARCLAY (A. W.), M. D.,

Assistant Physician to St. George's Hospital, &c.

A MANUAL OF MEDICAL DIAGNOSIS; being an Analysis of the Signs and Symptoms of Disease. Second American from the second and revised London edition. In one neat octavo volume, extra cloth, of 451 pages. \$2 25. (*Now ready.*)

The demand for a second edition of this work shows that the vacancy which it attempts to supply has been recognized by the profession, and that the efforts of the author to meet the want have been successful. The revision which it has enjoyed will render it better adapted than before to afford assistance to the learner in the prosecution of his studies, and to the practitioner who requires a convenient and accessible manual for speedy reference in the exigencies of his daily duties. For this latter purpose its complete and extensive Index renders it especially valuable, offering facilities for immediately turning to any class of symptoms, or any variety of disease.

The task of composing such a work is neither an easy nor a light one; but Dr. Barclay has performed it in a manner which meets our most unqualified approbation. He is no mere theorist; he knows his work thoroughly, and in attempting to perform it, has not exceeded his powers.—*British Med. Journal*.

We venture to predict that the work will be deservedly popular, and soon become, like Watson's Practice, an indispensable necessity to the practitioner.—*N. A. Med. Journal*.

An inestimable work of reference for the young practitioner and student.—*Nashville Med. Journal*.

We hope the volume will have an extensive circulation, not among students of medicine only, but practitioners also. They will never regret a faithful study of its pages.—*Cincinnati Lancet*.

An important acquisition to medical literature. It is a work of high merit, both from the vast importance of the subject upon which it treats, and also from the real ability displayed in its elaboration. In conclusion, let us bespeak for this volume that attention of every student of our art which it so richly deserves—that place in every medical library which it can so well adorn.—*Peninsular Medical Journal*.

BARTLETT (ELISHA), M. D.

THE HISTORY, DIAGNOSIS, AND TREATMENT OF THE FEVERS OF THE UNITED STATES. A new and revised edition. By ALONZO CLARK, M. D., Prof. of Pathology and Practical Medicine in the N. Y. College of Physicians and Surgeons, &c. In one octavo volume, of six hundred pages, extra cloth. Price \$3 00.

It is a work of great practical value and interest, containing much that is new relative to the several diseases of which it treats, and, with the additions of the editor, is fully up to the times. The distinctive features of the different forms of fever are plainly and forcibly portrayed, and the lines of demarcation carefully and accurately drawn, and to the American practitioner is a more valuable and safe guide than any work on fever extant.—*Ohio Med. and Surg. Journal*.

This excellent monograph on febrile disease, has

stood deservedly high since its first publication. It will be seen that it has now reached its fourth edition under the supervision of Prof. A. Clark, a gentleman who, from the nature of his studies and pursuits, is well calculated to appreciate and discuss the many intricate and difficult questions in pathology. His annotations add much to the interest of the work, and have brought it well up to the condition of the science as it exists at the present day in regard to this class of diseases.—*Southern Med. and Surg. Journal*.

BARWELL (RICHARD,) F. R. C. S.,
Assistant Surgeon Charing Cross Hospital, &c.

A TREATISE ON DISEASES OF THE JOINTS. Illustrated with engravings on wood. In one very handsome octavo volume, of about 500 pages, extra cloth; \$5 00.
(Now Ready.)

"A treatise on Diseases of the Joints equal to, or rather beyond the current knowledge of the day, has long been required—my professional brethren must judge whether the ensuing pages may supply the deficiency. No author is fit to estimate his own work at the moment of its completion, but it may be permitted me to say that the study of joint diseases has very much occupied my attention, even from my studentship, and that for the last six or eight years my devotion to that subject has been almost unremitting. . . . The real weight of my work has been at the bedside, and the greatest labor devoted to interpreting symptoms and remedying their cause."—AUTHOR'S PREFACE.

At the outset we may state that the work is worthy of much praise, and bears evidence of much thoughtful and careful inquiry, and here and there of no slight originality. We have already carried this notice further than we intended to do, but not to the extent the work deserves. We can only add, that the perusal of it has afforded us great pleasure. The author has evidently worked very hard at his subject, and his investigations into the Physiology and Pathology of Joints have been carried on in a manner which entitles him to be listened to with attention and respect. We must not omit to mention the very admirable plates with which the volume is enriched. We seldom meet with such striking and faithful delineations of disease.—*London Med. Times and Gazette*, Feb. 9, 1861.

We cannot take leave, however, of Mr. Barwell, without congratulating him on the interesting amount of information which he has compressed into his book. The work appears to us calculated

to be of much use to the practising surgeon who may be in want of a treatise on diseases of the joints, and at the same time one which contains the latest information on articular affections and the operations for their cure.—*Dublin Med. Press*, Feb. 27, 1861.

This volume will be welcomed, both by the pathologist and the surgeon, as being the record of much honest research and careful investigation into the nature and treatment of a most important class of disorders. We cannot conclude this notice of a valuable and useful book without calling attention to the amount of *bonâ fide* work it contains. In the present day of universal book-making, it is no slight matter for a volume to show laborious investigation, and at the same time original thought, on the part of its author, whom we may congratulate on the successful completion of his arduous task.—*London Lancet*, March 9, 1861.

CARPENTER (WILLIAM B.), M. D., F. R. S., &c.,
Examiner in Physiology and Comparative Anatomy in the University of London.

PRINCIPLES OF HUMAN PHYSIOLOGY; with their chief applications to Psychology, Pathology, Therapeutics, Hygiene, and Forensic Medicine. A new American, from the last and revised London edition. With nearly three hundred illustrations. Edited, with additions, by FRANCIS GURNEY SMITH, M. D., Professor of the Institutes of Medicine in the Pennsylvania Medical College, &c. In one very large and beautiful octavo volume, of about nine hundred large pages, handsomely printed and strongly bound in leather, with raised bands. \$4 25.

In the preparation of this new edition, the author has spared no labor to render it, as heretofore, a complete and lucid exposition of the most advanced condition of its important subject. The amount of the additions required to effect this object thoroughly, joined to the former large size of the volume, presenting objections arising from the unwieldy bulk of the work, he has omitted all those portions not bearing directly upon HUMAN PHYSIOLOGY, designing to incorporate them in his forthcoming Treatise on GENERAL PHYSIOLOGY. As a full and accurate text-book on the Physiology of Man, the work in its present condition therefore presents even greater claims upon the student and physician than those which have heretofore won for it the very wide and distinguished favor which it has so long enjoyed. The additions of Prof. Smith will be found to supply whatever may have been wanting to the American student, while the introduction of many new illustrations, and the most careful mechanical execution, render the volume one of the most attractive as yet issued.

For upwards of thirteen years Dr. Carpenter's work has been considered by the profession generally, both in this country and England, as the most valuable compendium on the subject of physiology in our language. This distinction it owes to the high attainments and unwearied industry of its accomplished author. The present edition (which, like the last American one, was prepared by the author himself), is the result of such extensive revision, that it may almost be considered a new work. We need hardly say, in concluding this brief notice, that while the work is indispensable to every student of medicine in this country, it will amply repay the practitioner for its perusal by the interest and value of its contents.—*Boston Med. and Surg. Journal*.

This is a standard work—the text-book used by all medical students who read the English language. It has passed through several editions in order to keep pace with the rapidly growing science of Physiology. Nothing need be said in its praise, for its merits are universally known; we have nothing to say of its defects, for they only appear where the science of which it treats is incomplete.—*Western Lancet*.

The most complete exposition of physiology which any language can at present give.—*Brit. and For. Med.-Chirurg. Review*.

The greatest, the most reliable, and the best book on the subject which we know of in the English language.—*Stethoscope*.

To eulogize this great work would be superfluous. We should observe, however, that in this edition the author has remodelled a large portion of the former, and the editor has added much matter of interest, especially in the form of illustrations. We may confidently recommend it as the most complete work on Human Physiology in our language.—*Southern Med. and Surg. Journal*.

The most complete work on the science in our language.—*Am. Med. Journal*.

The most complete work now extant in our language.—*N. O. Med. Register*.

The best text-book in the language on this extensive subject.—*London Med. Times*.

A complete cyclopaedia of this branch of science.—*N. Y. Med. Times*.

The profession of this country, and perhaps also of Europe, have anxiously and for some time awaited the announcement of this new edition of Carpenter's Human Physiology. His former editions have for many years been almost the only text-book on Physiology in all our medical schools, and its circulation among the profession has been unsurpassed by any work in any department of medical science.

It is quite unnecessary for us to speak of this work as its merits would justify. The mere announcement of its appearance will afford the highest pleasure to every student of Physiology, while its perusal will be of infinite service in advancing physiological science.—*Ohio Med. and Surg. Journal*.

CARPENTER (WILLIAM B.), M. D., F. R. S.,

Examiner in Physiology and Comparative Anatomy in the University of London.

THE MICROSCOPE AND ITS REVELATIONS. With an Appendix containing the Applications of the Microscope to Clinical Medicine, &c. By F. G. SMITH, M. D. Illustrated by four hundred and thirty-four beautiful engravings on wood. In one large and very handsome octavo volume, of 724 pages, extra cloth, \$4 00; leather, \$4 50.

Dr. Carpenter's position as a microscopist and physiologist, and his great experience as a teacher, eminently qualify him to produce what has long been wanted—a good text-book on the practical use of the microscope. In the present volume his object has been, as stated in his Preface, “to combine, within a moderate compass, that information with regard to the use of his ‘tools,’ which is most essential to the working microscopist, with such an account of the objects best fitted for his study, as might qualify him to comprehend what he observes, and might thus prepare him to benefit science, whilst expanding and refreshing his own mind.” That he has succeeded in accomplishing this, no one acquainted with his previous labors can doubt.

The great importance of the microscope as a means of diagnosis, and the number of microscopists who are also physicians, have induced the American publishers, with the author's approval, to add an Appendix, carefully prepared by Professor Smith, on the applications of the instrument to clinical medicine, together with an account of American Microscopes, their modifications and accessories. This portion of the work is illustrated with nearly one hundred wood-cuts, and, it is hoped, will adapt the volume more particularly to the use of the American student.

Those who are acquainted with Dr. Carpenter's previous writings on Animal and Vegetable Physiology, will fully understand how vast a store of knowledge he is able to bring to bear upon so comprehensive a subject as the revelations of the microscope; and even those who have no previous acquaintance with the construction or uses of this instrument, will find abundance of information conveyed in clear and simple language.—*Med. Times and Gazette.*

Although originally not intended as a strictly

medical work, the additions by Prof. Smith give it a positive claim upon the profession, for which we doubt not he will receive their sincere thanks. Indeed, we know not where the student of medicine will find such a complete and satisfactory collection of microscopic facts bearing upon physiology and practical medicine as is contained in Prof. Smith's appendix; and this of itself, it seems to us, is fully worth the cost of the volume.—*Louisville Medical Review.*

BY THE SAME AUTHOR.

ELEMENTS (OR MANUAL) OF PHYSIOLOGY, INCLUDING PHYSIOLOGICAL ANATOMY. Second American, from a new and revised London edition. With one hundred and ninety illustrations. In one very handsome octavo volume, leather. pp. 566. \$3 00.

In publishing the first edition of this work, its title was altered from that of the London volume, by the substitution of the word “Elements” for that of “Manual,” and with the author's sanction the title of “Elements” is still retained as being more expressive of the scope of the treatise.

To say that it is the best manual of Physiology now before the public, would not do sufficient justice to the author.—*Buffalo Medical Journal.*

In his former works it would seem that he had exhausted the subject of Physiology. In the present, he gives the essence, as it were, of the whole.—*N. Y. Journal of Medicine.*

Those who have occasion for an elementary treatise on Physiology, cannot do better than to possess themselves of the manual of Dr. Carpenter.—*Medical Examiner.*

The best and most complete exposé of modern Physiology, in one volume, extant in the English language.—*St. Louis Medical Journal.*

BY THE SAME AUTHOR.

PRINCIPLES OF COMPARATIVE PHYSIOLOGY. New American, from the Fourth and Revised London edition. In one large and handsome octavo volume, with over three hundred beautiful illustrations. pp. 752. Extra cloth, \$4 80; leather, raised bands, \$5 25.

This book should not only be read but thoroughly studied by every member of the profession. None are too wise or old, to be benefited thereby. But especially to the younger class would we cordially commend it as best fitted of any work in the English language to qualify them for the reception and comprehension of those truths which are daily being developed in physiology.—*Medical Censor.*

Without pretending to it, it is an encyclopedia of the subject, accurate and complete in all respects—a truthful reflection of the advanced state at which the science has now arrived.—*Dublin Quarterly Journal of Medical Science.*

A truly magnificent work—in itself a perfect physiological study.—*Ranking's Abstract.*

This work stands without its fellow. It is one few men in Europe could have undertaken; it is one

no man, we believe, could have brought to so successful an issue as Dr. Carpenter. It required for its production a physiologist at once deeply read in the labors of others, capable of taking a general, critical, and unprejudiced view of those labors, and of combining the varied, heterogeneous materials at his disposal, so as to form an harmonious whole. We feel that this abstract can give the reader a very imperfect idea of the fulness of this work, and no idea of its unity, of the admirable manner in which material has been brought, from the most various sources, to conduce to its completeness, of the lucidity of the reasoning it contains, or of the clearness of language in which the whole is clothed. Not the profession only, but the scientific world at large, must feel deeply indebted to Dr. Carpenter for this great work. It must, indeed, add largely even to his high reputation.—*Medical Times.*

BY THE SAME AUTHOR. (Preparing.)

PRINCIPLES OF GENERAL PHYSIOLOGY, INCLUDING ORGANIC CHEMISTRY AND HISTOLOGY. With a General Sketch of the Vegetable and Animal Kingdom. In one large and very handsome octavo volume, with several hundred illustrations.

BY THE SAME AUTHOR.

A PRIZE ESSAY ON THE USE OF ALCOHOLIC LIQUORS IN HEALTH AND DISEASE. New edition, with a Preface by D. F. CONDIE, M. D., and explanations of scientific words. In one neat 12mo. volume, extra cloth. pp. 178. 50 cents.

CONDIE (D. F.), M. D., &c.

A PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Fifth edition, revised and augmented. In one large volume, 8vo., leather, of over 750 pages. \$3 25. (Just Issued, 1859.)

In presenting a new and revised edition of this favorite work, the publishers have only to state that the author has endeavored to render it in every respect "a complete and faithful exposition of the pathology and therapeutics of the maladies incident to the earlier stages of existence—a full and exact account of the diseases of infancy and childhood." To accomplish this he has subjected the whole work to a careful and thorough revision, rewriting a considerable portion, and adding several new chapters. In this manner it is hoped that any deficiencies which may have previously existed have been supplied, that the recent labors of practitioners and observers have been thoroughly incorporated, and that in every point the work will be found to maintain the high reputation it has enjoyed as a complete and thoroughly practical book of reference in infantile affections.

A few notices of previous editions are subjoined.

Dr. Condie's scholarship, acumen, industry, and practical sense are manifested in this, as in all his numerous contributions to science.—*Dr. Holmes's Report to the American Medical Association.*

Taken as a whole, in our judgment, Dr. Condie's Treatise is the one from the perusal of which the practitioner in this country will rise with the greatest satisfaction.—*Western Journal of Medicine and Surgery.*

One of the best works upon the Diseases of Children in the English language.—*Western Lancet.*

We feel assured from actual experience that no physician's library can be complete without a copy of this work.—*N. Y. Journal of Medicine.*

A veritable pædiatric encyclopædia, and an honor to American medical literature.—*Ohio Medical and Surgical Journal.*

We feel persuaded that the American medical profession will soon regard it not only as a very good, but as the VERY BEST "Practical Treatise on the Diseases of Children."—*American Medical Journal.*

In the department of infantile therapeutics, the work of Dr. Condie is considered one of the best which has been published in the English language.—*The Stethoscope.*

We pronounced the first edition to be the best work on the diseases of children in the English language, and, notwithstanding all that has been published, we still regard it in that light.—*Medical Examiner.*

The value of works by native authors on the diseases which the physician is called upon to combat, will be appreciated by all; and the work of Dr. Condie has gained for itself the character of a safe guide for students, and a useful work for consultation by those engaged in practice.—*N. Y. Med. Times.*

This is the fourth edition of this deservedly popular treatise. During the interval since the last edition, it has been subjected to a thorough revision by the author; and all new observations in the pathology and therapeutics of children have been included in the present volume. As we said before, we do not know of a better book on diseases of children, and to a large part of its recommendations we yield an unhesitating concurrence.—*Buffalo Med. Journal.*

Perhaps the most full and complete work now before the profession of the United States; indeed, we may say in the English language. It is vastly superior to most of its predecessors.—*Transylvania Med. Journal.*

CHRISTISON (ROBERT), M. D., V. P. R. S. E., &c.

A DISPENSATORY; or, Commentary on the Pharmacopœias of Great Britain and the United States; comprising the Natural History, Description, Chemistry, Pharmacy, Actions, Uses, and Doses of the Articles of the Materia Medica. Second edition, revised and improved, with a Supplement containing the most important New Remedies. With copious Additions, and two hundred and thirteen large wood-engravings. By R. EGLESFELD GRIFFITH, M. D. In one very large and handsome octavo volume, leather, raised bands, of over 1000 pages. \$3 50.

COOPER (BRANSBY B.), F. R. S.

LECTURES ON THE PRINCIPLES AND PRACTICE OF SURGERY. In one very large octavo volume, extra cloth, of 750 pages. \$3 00.

COOPER ON DISLOCATIONS AND FRACTURES OF THE JOINTS.—Edited by BRANSBY B. COOPER, F. R. S., &c. With additional Observations by Prof. J. C. WARREN. A new American edition. In one handsome octavo volume, extra cloth, of about 500 pages, with numerous illustrations on wood. \$3 25.

COOPER ON THE ANATOMY AND DISEASES OF THE BREAST, with twenty-five Miscellaneous and Surgical Papers. One large volume, imperial 8vo., extra cloth, with 252 figures, on 36 plates. \$2 50.

COOPER ON THE STRUCTURE AND DISEASES OF THE TESTIS, AND ON THE THYMUS GLAND. One vol. imperial 8vo., extra cloth, with 177 figures on 29 plates. \$2 00.

COPLAND ON THE CAUSES, NATURE, AND TREATMENT OF PALSY AND APOPLEXY. In one volume, royal 12mo., extra cloth. pp. 326. 80 cents.

CLYMER ON FEVERS; THEIR DIAGNOSIS, PATHOLOGY, AND TREATMENT In one octavo volume, leather, of 600 pages. \$1 50.

COLOMBAT DE L'ISERE ON THE DISEASES OF FEMALES, and on the special Hygiene of their Sex. Translated, with many Notes and Additions, by C. D. MEIGS, M. D. Second edition, revised and improved. In one large volume, octavo, leather, with numerous wood-cuts. pp. 720. \$3 50.

CARSON (JOSEPH), M. D.,

Professor of Materia Medica and Pharmacy in the University of Pennsylvania.

SYNOPSIS OF THE COURSE OF LECTURES ON MATERIA MEDICA AND PHARMACY, delivered in the University of Pennsylvania. Second and revised edition. In one very neat octavo volume, extra cloth, of 208 pages. \$1 50.

CURLING (T. B.), F. R. S.,

Surgeon to the London Hospital, President of the Hunterian Society, &c.

A PRACTICAL TREATISE ON DISEASES OF THE TESTIS, SPERMATIC CORD, AND SCROTUM. Second American, from the second and enlarged English edition. In one handsome octavo volume, extra cloth, with numerous illustrations. pp. 420. \$2 00.

CHURCHILL (FLEETWOOD), M. D., M. R. I. A.

ON THE THEORY AND PRACTICE OF MIDWIFERY. A new American from the fourth revised and enlarged London edition. With Notes and Additions, by D. FRANCIS CONDIE, M. D., author of a "Practical Treatise on the Diseases of Children," &c. With 194 illustrations. In one very handsome octavo volume, leather, of nearly 700 large pages. \$3 50. (Just Issued.)

This work has been so long an established favorite, both as a text-book for the learner and as a reliable aid in consultation for the practitioner, that in presenting a new edition it is only necessary to call attention to the very extended improvements which it has received. Having had the benefit of two revisions by the author since the last American reprint, it has been materially enlarged, and Dr. Churchill's well-known conscientious industry is a guarantee that every portion has been thoroughly brought up with the latest results of European investigation in all departments of the science and art of obstetrics. The recent date of the last Dublin edition has not left much of novelty for the American editor to introduce, but he has endeavored to insert whatever has since appeared, together with such matters as his experience has shown him would be desirable for the American student, including a large number of illustrations. With the sanction of the author he has added in the form of an appendix, some chapters from a little "Manual for Midwives and Nurses," recently issued by Dr. Churchill, believing that the details there presented can hardly fail to prove of advantage to the junior practitioner. The result of all these additions is that the work now contains fully one-half more matter than the last American edition, with nearly one-half more illustrations, so that notwithstanding the use of a smaller type, the volume contains almost two hundred pages more than before.

No effort has been spared to secure an improvement in the mechanical execution of the work equal to that which the text has received, and the volume is confidently presented as one of the handsomest that has thus far been laid before the American profession; while the very low price at which it is offered should secure for it a place in every lecture-room and on every office table.

A better book in which to learn these important points we have not met than Dr. Churchill's. Every page of it is full of instruction; the opinion of all writers of authority is given on questions of difficulty, as well as the directions and advice of the learned author himself, to which he adds the result of statistical inquiry, putting statistics in their proper place and giving them their due weight, and no more. We have never read a book more free from professional jealousy than Dr. Churchill's. It appears to be written with the true design of a book on medicine, viz.: to give all that is known on the subject of which he treats, both theoretically and practically, and to advance such opinions of his own as he believes will benefit medical science, and insure the safety of the patient. We have said enough to convey to the profession that this book of Dr. Churchill's is admirably suited for a book of reference for the practitioner, as well as a text-book for the student, and we hope it may be extensively purchased amongst our readers. To them we most strongly recommend it.—*Dublin Medical Press*, June 20, 1860.

To bestow praise on a book that has received such marked approbation would be superfluous. We need only say, therefore, that if the first edition was thought worthy of a favorable reception by the medical public, we can confidently affirm that this will be found much more so. The lecturer, the practitioner, and the student, may all have recourse to its pages, and derive from their perusal much interest and instruction in everything relating to theoretical and practical midwifery.—*Dublin Quarterly Journal of Medical Science*.

A work of very great merit, and such as we can confidently recommend to the study of every obstetric practitioner.—*London Medical Gazette*.

This is certainly the most perfect system extant. It is the best adapted for the purposes of a text-book, and that which he whose necessities confine him to one book, should select in preference to all others.—*Southern Medical and Surgical Journal*.

BY THE SAME AUTHOR. (Lately Published.)

ON THE DISEASES OF INFANTS AND CHILDREN. Second American Edition, revised and enlarged by the author. Edited, with Notes, by W. V. KEATING, M. D. In one large and handsome volume, extra cloth, of over 700 pages. \$3 00, or in leather, \$3 25.

In preparing this work a second time for the American profession, the author has spared no labor in giving it a very thorough revision, introducing several new chapters, and rewriting others, while every portion of the volume has been subjected to a severe scrutiny. The efforts of the American editor have been directed to supplying such information relative to matters peculiar to this country as might have escaped the attention of the author, and the whole may, therefore, be safely pronounced one of the most complete works on the subject accessible to the American Profession. By an alteration in the size of the page, these very extensive additions have been accommodated without unduly increasing the size of the work.

BY THE SAME AUTHOR.

ESSAYS ON THE PUERPERAL FEVER, AND OTHER DISEASES PECULIAR TO WOMEN. Selected from the writings of British Authors previous to the close of the Eighteenth Century. In one neat octavo volume, extra cloth, of about 450 pages. \$2 50.

The most popular work on midwifery ever issued from the American press.—*Charleston Med. Journal*.

Were we reduced to the necessity of having but one work on midwifery, and permitted to choose, we would unhesitatingly take Churchill.—*Western Med. and Surg. Journal*.

It is impossible to conceive a more useful and elegant manual than Dr. Churchill's Practice of Midwifery.—*Provincial Medical Journal*.

Certainly, in our opinion, the very best work on he subject which exists.—*N. Y. Analyst*.

No work holds a higher position, or is more deserving of being placed in the hands of the tyro, the advanced student, or the practitioner.—*Medical Examiner*.

Previous editions, under the editorial supervision of Prof. R. M. Huston, have been received with marked favor, and they deserved it; but this, reprinted from a very late Dublin edition, carefully revised and brought up by the author to the present time, does present an unusually accurate and able exposition of every important particular embraced in the department of midwifery. * * The clearness, directness, and precision of its teachings, together with the great amount of statistical research which its text exhibits, have served to place it already in the foremost rank of works in this department of medical science.—*N. O. Med. and Surg. Journal*.

In our opinion, it forms one of the best if not the very best text-book and epitome of obstetric science which we at present possess in the English language.—*Monthly Journal of Medical Science*.

The clearness and precision of style in which it is written, and the great amount of statistical research which it contains, have served to place it in the first rank of works in this department of medical science.—*N. Y. Journal of Medicine*.

Few treatises will be found better adapted as a text-book for the student, or as a manual for the frequent consultation of the young practitioner.—*American Medical Journal*.

CHURCHILL (FLEETWOOD), M. D., M. R. I. A., &c.
ON THE DISEASES OF WOMEN; including those of Pregnancy and Child-bed. A new American edition, revised by the Author. With Notes and Additions, by D. FRANKS CONDIE, M. D., author of "A Practical Treatise on the Diseases of Children." With numerous illustrations. In one large and handsome octavo volume, leather, of 768 pages. \$3 00.

This edition of Dr. Churchill's very popular treatise may almost be termed a new work, so thoroughly has he revised it in every portion. It will be found greatly enlarged, and completely brought up to the most recent condition of the subject, while the very handsome series of illustrations introduced, representing such pathological conditions as can be accurately portrayed, present a novel feature, and afford valuable assistance to the young practitioner. Such additions as appeared desirable for the American student have been made by the editor, Dr. Condie, while a marked improvement in the mechanical execution keeps pace with the advance in all other respects which the volume has undergone, while the price has been kept at the former very moderate rate.

It comprises, unquestionably, one of the most exact and comprehensive expositions of the present state of medical knowledge in respect to the diseases of women that has yet been published.—*Am. Journ. Med. Sciences.*

This work is the most reliable which we possess on this subject; and is deservedly popular with the profession.—*Charleston Med. Journal*, July, 1857.

We know of no author who deserves that approbation, on "the diseases of females," to the same

extent that Dr. Churchill does. His, indeed, is the only thorough treatise we know of on the subject; and it may be commended to practitioners and students as a masterpiece in its particular department.—*The Western Journal of Medicine and Surgery.*

As a comprehensive manual for students, or a work of reference for practitioners, it surpasses any other that has ever issued on the same subject from the British press.—*Dublin Quart. Journal.*

DICKSON (S. H.), M. D.,
 Professor of Practice of Medicine in the Jefferson Medical College, Philadelphia.
ELEMENTS OF MEDICINE; a Compendious View of Pathology and Therapeutics, or the History and Treatment of Diseases. Second edition, revised. In one large and handsome octavo volume of 750 pages, leather. \$3 75. (*Just Issued.*)

The steady demand which has so soon exhausted the first edition of this work, sufficiently shows that the author was not mistaken in supposing that a volume of this character was needed—an elementary manual of practice, which should present the leading principles of medicine with the practical results, in a condensed and perspicuous manner. Disencumbered of unnecessary detail and fruitless speculations, it embodies what is most requisite for the student to learn, and at the same time what the active practitioner wants when obliged, in the daily calls of his profession, to refresh his memory on special points. The clear and attractive style of the author renders the whole easy of comprehension, while his long experience gives to his teachings an authority everywhere acknowledged. Few physicians, indeed, have had wider opportunities for observation and experience, and few, perhaps, have used them to better purpose. As the result of a long life devoted to study and practice, the present edition, revised and brought up to the date of publication, will doubtless maintain the reputation already acquired as a condensed and convenient American text-book on the Practice of Medicine.

DRUITT (ROBERT), M. R. C. S., &c.
THE PRINCIPLES AND PRACTICE OF MODERN SURGERY. A new and revised American from the eighth enlarged and improved London edition. Illustrated with four hundred and thirty-two wood-engravings. In one very handsomely printed octavo volume, leather, of nearly 700 large pages. \$3 50. (*Just Issued.*)

A work which like DRUITT'S SURGERY has for so many years maintained the position of a leading favorite with all classes of the profession, needs no special recommendation to attract attention to a revised edition. It is only necessary to state that the author has spared no pains to keep the work up to its well earned reputation of presenting in a small and convenient compass the latest condition of every department of surgery, considered both as a science and as an art; and that the services of a competent American editor have been employed to introduce whatever novelties may have escaped the author's attention, or may prove of service to the American practitioner. As several editions have appeared in London since the issue of the last American reprint, the volume has had the benefit of repeated revisions by the author, resulting in a very thorough alteration and improvement. The extent of these additions may be estimated from the fact that it now contains about one-third more matter than the previous American edition, and that notwithstanding the adoption of a smaller type, the pages have been increased by about one hundred, while nearly two hundred and fifty wood-cuts have been added to the former list of illustrations.

A marked improvement will also be perceived in the mechanical and artistical execution of the work, which, printed in the best style, on new type, and fine paper, leaves little to be desired as regards external finish; while at the very low price affixed it will be found one of the cheapest volumes accessible to the profession.

This popular volume, now a most comprehensive work on surgery, has undergone many corrections, improvements, and additions, and the principles and the practice of the art have been brought down to the latest record and observation. Of the operations in surgery it is impossible to speak too highly. The descriptions are so clear and concise, and the illustrations so accurate and numerous, that the student can have no difficulty, with instrument in hand, and book by his side, over the dead body, in obtaining a proper knowledge and sufficient tact in this much neglected department of medical education.—*British and Foreign Medico-Chirurg. Review*, Jan. 1860.

In the present edition the author has entirely rewritten many of the chapters, and has incorporated the various improvements and additions in modern surgery. On carefully going over it, we find that

nothing of real practical importance has been omitted; it presents a faithful epitome of everything relating to surgery up to the present hour. It is deservedly a popular manual, both with the student and practitioner.—*London Lancet*, Nov. 19, 1859.

In closing this brief notice, we recommend as cordially as ever this most useful and comprehensive hand-book. It must prove a vast assistance, not only to the student of surgery, but also to the busy practitioner who may not have the leisure to devote himself to the study of more lengthy volumes.—*London Med. Times and Gazette*, Oct. 22, 1859.

In a word, this eighth edition of Dr. Drutt's Manual of Surgery is all that the surgical student or practitioner could desire.—*Dublin Quarterly Journal of Med. Sciences*, Nov. 1859.

DALTON, JR. (J. C.), M. D.

Professor of Physiology in the College of Physicians, New York.

A TREATISE ON HUMAN PHYSIOLOGY, designed for the use of Students and Practitioners of Medicine. Second edition, revised and enlarged, with two hundred and seventy-one illustrations on wood. In one very beautiful octavo volume, of 700 pages, extra cloth, \$4 00; leather, raised bands, \$4 50. (*Just Issued*, 1861.)

The general favor which has so soon exhausted an edition of this work has afforded the author an opportunity in its revision of supplying the deficiencies which existed in the former volume. This has caused the insertion of two new chapters—one on the Special Senses, the other on Inhibition, Exhalation, and the Functions of the Lymphatic System—besides numerous additions of smaller amount scattered through the work, and a general revision designed to bring it thoroughly up to the present condition of the science with regard to all points which may be considered as definitely settled. A number of new illustrations has been introduced, and the work, it is hoped, in its improved form, may continue to command the confidence of those for whose use it is intended.

It will be seen, therefore, that Dr. Dalton's best efforts have been directed towards perfecting his work. The additions are marked by the same features which characterize the remainder of the volume, and render it by far the most desirable text-book on physiology to place in the hands of the student which, so far as we are aware, exists in the English language, or perhaps in any other. We therefore have no hesitation in recommending Dr. Dalton's book for the classes for which it is intended, satisfied as we are that it is better adapted to their use than any other work of the kind to which they have access.—*American Journal of the Medical Sciences*, April, 1861.

It is, therefore, no disparagement to the many books upon physiology, most excellent in their day, to say that Dalton's is the only one that gives us the science as it was known to the best philosophers throughout the world, at the beginning of the current year. It states in comprehensive but concise diction, the facts established by experiment, or other method of demonstration, and details, in an understandable manner, how it is done, but abstains from the discussion of unsettled or theoretical points. Herein it is unique; and these characteristics render it a text-book without a rival, for those who desire to study physiological science as it is known to its most successful cultivators. And it is physiology thus presented that lies at the foundation of correct pathological knowledge; and this in turn is the basis of rational therapeutics; so that pathology, in fact, becomes of prime importance in the proper discharge of our every-day practical duties.—*Cincinnati Lancet*, May, 1861.

Dr. Dalton needs no word of praise from us. He is universally recognized as among the first, if not the very first, of American physiologists now living. The first edition of his admirable work appeared but two years since, and the advance of science, his

own original views and experiments, together with a desire to supply what he considered some deficiencies in the first edition, have already made the present one a necessity, and it will no doubt be even more eagerly sought for than the first. That it is not merely a reprint, will be seen from the author's statement of the following principal additions and alterations which he has made. The present, like the first edition, is printed in the highest style of the printer's art, and the illustrations are truly admirable for their clearness in expressing exactly what their author intended.—*Boston Medical and Surgical Journal*, March 23, 1861.

It is unnecessary to give a detail of the additions; suffice it to say, that they are numerous and important, and such as will render the work still more valuable and acceptable to the profession as a learned and original treatise on this all-important branch of medicine. All that was said in commendation of the getting up of the first edition, and the superior style of the illustrations apply with equal force to this. No better work on physiology can be placed in the hand of the student.—*St. Louis Medical and Surgical Journal*, May, 1861.

These additions, while testifying to the learning and industry of the author, render the book exceedingly useful, as the most complete exposé of a science, of which Dr. Dalton is doubtless the ablest representative on this side of the Atlantic.—*New Orleans Med. Times*, May, 1861.

A second edition of this deservedly popular work having been called for in the short space of two years, the author has supplied deficiencies, which existed in the former volume, and has thus more completely fulfilled his design of presenting to the profession a reliable and precise text-book, and one which we consider the best outline on the subject of which it treats, in any language.—*N. American Medico-Chirurg. Review*, May, 1861.

DUNGLISON, FORBES, TWEEDIE, AND CONOLLY.

THE CYCLOPÆDIA OF PRACTICAL MEDICINE: comprising Treatises on the Nature and Treatment of Diseases, Materia Medica, and Therapeutics, Diseases of Women and Children, Medical Jurisprudence, &c. &c. In four large super-royal octavo volumes, of 3254 double-columned pages, strongly and handsomely bound, with raised bands. \$12 00.

*** This work contains no less than four hundred and eighteen distinct treatises, contributed by sixty-eight distinguished physicians, rendering it a complete library of reference for the country practitioner.

The most complete work on Practical Medicine extant; or, at least, in our language.—*Buffalo Medical and Surgical Journal*.

For reference, it is above all price to every practitioner.—*Western Lancet*.

One of the most valuable medical publications of the day—as a work of reference it is invaluable.—*Western Journal of Medicine and Surgery*.

It has been to us, both as learner and teacher, a work for ready and frequent reference, one in which modern English medicine is exhibited in the most advantageous light.—*Medical Examiner*.

The editors are practitioners of established reputation, and the list of contributors embraces many of the most eminent professors and teachers of London, Edinburgh, Dublin, and Glasgow. It is, indeed, the great merit of this work that the principal articles have been furnished by practitioners who have not only devoted especial attention to the diseases about which they have written, but have also enjoyed opportunities for an extensive practical acquaintance with them and whose reputation carries the assurance of their competency justly to appreciate the opinions of others, while it stamps their own doctrines with high and just authority.—*American Medical Journal*.

DEWEES'S COMPREHENSIVE SYSTEM OF MIDWIFERY. Illustrated by occasional cases and many engravings. Twelfth edition, with the author's last improvements and corrections. In one octavo volume, extra cloth, of 600 pages. \$3 20.

DEWEES'S TREATISE ON THE PHYSICAL

AND MEDICAL TREATMENT OF CHILDREN. The last edition. In one volume, octavo, extra cloth, 548 pages. \$2 50.

DEWEES'S TREATISE ON THE DISEASES OF FEMALES. Tenth edition. In one volume, octavo extra cloth, 532 pages, with plates. \$3 00.

DUNGLISON (ROBLEY), M. D.,

Professor of Institutes of Medicine in the Jefferson Medical College, Philadelphia.

NEW AND ENLARGED EDITION.

MEDICAL LEXICON; a Dictionary of Medical Science, containing a concise Explanation of the various Subjects and Terms of Anatomy, Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Medical Jurisprudence, Dentistry, &c. Notices of Climate and of Mineral Waters; Formulæ for Official, Empirical, and Dietetic Preparations, &c. With French and other Synonymes. Revised and very greatly enlarged. In one very large and handsome octavo volume, of 992 double-columned pages, in small type; strongly bound in leather, with raised bands. Price \$4 00.

Especial care has been devoted in the preparation of this edition to render it in every respect worthy a continuance of the very remarkable favor which it has hitherto enjoyed. The rapid sale of FIFTEEN large editions, and the constantly increasing demand, show that it is regarded by the profession as the standard authority. Stimulated by this fact, the author has endeavored in the present revision to introduce whatever might be necessary "to make it a satisfactory and desirable—if not indispensable—lexicon, in which the student may search without disappointment for every term that has been legitimated in the nomenclature of the science." To accomplish this, large additions have been found requisite, and the extent of the author's labors may be estimated from the fact that about SIX THOUSAND subjects and terms have been introduced throughout, rendering the whole number of definitions about SIXTY THOUSAND, to accommodate which, the number of pages has been increased by nearly a hundred, notwithstanding an enlargement in the size of the page. The medical press, both in this country and in England, has pronounced the work indispensable to all medical students and practitioners, and the present improved edition will not lose that enviable reputation.

The publishers have endeavored to render the mechanical execution worthy of a volume of such universal use in daily reference. The greatest care has been exercised to obtain the typographical accuracy so necessary in a work of the kind. By the small but exceedingly clear type employed, an immense amount of matter is condensed in its thousand ample pages, while the binding will be found strong and durable. With all these improvements and enlargements, the price has been kept at the former very moderate rate, placing it within the reach of all.

This work, the appearance of the fifteenth edition of which, it has become our duty and pleasure to announce, is perhaps the most stupendous monument of labor and erudition in medical literature. One would hardly suppose after constant use of the preceding editions, where we have never failed to find a sufficiently full explanation of every medical term, that in this edition "about six thousand subjects and terms have been added," with a careful revision and correction of the entire work. It is only necessary to announce the advent of this edition to make it occupy the place of the preceding one on the table of every medical man, as it is without doubt the best and most comprehensive work of the kind which has ever appeared.—*Buffalo Med. Journ.*, Jan. 1858.

The work is a monument of patient research, skilful judgment, and vast physical labor, that will perpetuate the name of the author more effectually than any possible device of stone or metal. Dr. Dunglison deserves the thanks not only of the American profession, but of the whole medical world.—*North Am. Medico-Chir. Review*, Jan. 1858.

A Medical Dictionary better adapted for the wants of the profession than any other with which we are acquainted, and of a character which places it far above comparison and competition.—*Am. Journ. Med. Sciences*, Jan. 1858.

We need only say, that the addition of 6,000 new terms, with their accompanying definitions, may be said to constitute a new work, by itself. We have examined the Dictionary attentively, and are most happy to pronounce it unrivalled of its kind. The erudition displayed, and the extraordinary industry which must have been demanded, in its preparation and perfection, redound to the lasting credit of its author, and have furnished us with a volume indispensable at the present day, to all who would find themselves *au niveau* with the highest standards of medical information.—*Boston Medical and Surgical Journal*, Dec. 31, 1857.

Good lexicons and encyclopedic works generally, are the most labor-saving contrivances which literary men enjoy; and the labor which is required to produce them in the perfect manner of this example is something appalling to contemplate. The author

tells us in his preface that he has added about six thousand terms and subjects to this edition, which, before, was considered universally as the best work of the kind in any language.—*Silliman's Journal*, March, 1855.

He has razed his gigantic structure to the foundations, and remodelled and reconstructed the entire pile. No less than six thousand additional subjects and terms are illustrated and analyzed in this new edition, swelling the grand aggregate to beyond sixty thousand! Thus is placed before the profession a complete and thorough exponent of medical terminology, without rival or possibility of rivalry.—*Nashville Journ. of Med. and Surg.*, Jan. 1858.

It is universally acknowledged, we believe, that this work is incomparably the best and most complete Medical Lexicon in the English language. The amount of labor which the distinguished author has bestowed upon it is truly wonderful, and the learning and research displayed in its preparation are equally remarkable. Comment and commendation are unnecessary, as no one at the present day thinks of purchasing any other Medical Dictionary than this.—*St. Louis Med. and Surg. Journ.*, Jan. 1858.

It is the foundation stone of a good medical library, and should always be included in the first list of books purchased by the medical student.—*Am. Med. Monthly*, Jan. 1858.

A very perfect work of the kind, undoubtedly the most perfect in the English language.—*Med. and Surg. Reporter*, Jan. 1858.

It is now emphatically the Medical Dictionary of the English language, and for it there is no substitute.—*N. H. Med. Journ.*, Jan. 1858.

It is scarcely necessary to remark that any medical library wanting a copy of Dunglison's Lexicon must be imperfect.—*Cin. Lancet*, Jan. 1858.

We have ever considered it the best authority published, and the present edition we may safely say has no equal in the world.—*Peninsular Med. Journal*, Jan. 1858.

The most complete authority on the subject to be found in any language.—*Va. Med. Journal*, Feb. '58.

BY THE SAME AUTHOR.

THE PRACTICE OF MEDICINE. A Treatise on Special Pathology and Therapeutics. Third Edition. In two large octavo volumes, leather, of 1,500 pages. \$6 25.

DUNGLISON (ROBLEY), M. D.,

Professor of Institutes of Medicine in the Jefferson Medical College, Philadelphia.

HUMAN PHYSIOLOGY. Eighth edition. Thoroughly revised and extensively modified and enlarged, with five hundred and thirty-two illustrations. In two large and handsomely printed octavo volumes, leather, of about 1500 pages. \$7 00.

In revising this work for its eighth appearance, the author has spared no labor to render it worthy a continuance of the very great favor which has been extended to it by the profession. The whole contents have been rearranged, and to a great extent remodelled; the investigations which of late years have been so numerous and so important, have been carefully examined and incorporated, and the work in every respect has been brought up to a level with the present state of the subject. The object of the author has been to render it a concise but comprehensive treatise, containing the whole body of physiological science, to which the student and man of science can at all times refer with the certainty of finding whatever they are in search of, fully presented in all its aspects; and on no former edition has the author bestowed more labor to secure this result.

We believe that it can truly be said, no more complete repository of facts upon the subject treated, can anywhere be found. The author has, moreover, that enviable tact at description and that facility and ease of expression which render him peculiarly acceptable to the casual, or the studious reader. This faculty, so requisite in setting forth many graver and less attractive subjects, lends additional charms to one always fascinating.—*Boston Med. and Surg. Journal*.

The most complete and satisfactory system of Physiology in the English language.—*Amer. Med. Journal*.

The best work of the kind in the English language.—*Silliman's Journal*.

The present edition the author has made a perfect mirror of the science as it is at the present hour. As a work upon physiology proper, the science of the functions performed by the body, the student will find it all he wishes.—*Nashville Journ. of Med.*

That he has succeeded, most admirably succeeded in his purpose, is apparent from the appearance of an eighth edition. It is now the great encyclopædia on the subject, and worthy of a place in every physician's library.—*Western Lancet*.

BY THE SAME AUTHOR. (*A new edition.*)

GENERAL THERAPEUTICS AND MATERIA MEDICA; adapted for a Medical Text-book. With Indexes of Remedies and of Diseases and their Remedies. SIXTH EDITION, revised and improved. With one hundred and ninety-three illustrations. In two large and handsomely printed octavo vols., leather, of about 1100 pages. \$6 00.

In announcing a new edition of Dr. Dunglison's General Therapeutics and Materia Medica, we have no words of commendation to bestow upon a work whose merits have been heretofore so often and so justly extolled. It must not be supposed, however, that the present is a mere reprint of the previous edition; the character of the author for laborious research, judicious analysis, and clearness of expression, is fully sustained by the numerous additions he has made to the work, and the careful revision to which he has subjected the whole.—*N. A. Medico-Chir. Review*, Jan. 1858.

The work will, we have little doubt, be bought and read by the majority of medical students; its size, arrangement, and reliability recommend it to all; no one, we venture to predict, will study it without profit, and there are few to whom it will not be in some measure useful as a work of reference. The young practitioner, more especially, will find the copious indexes appended to this edition of great assistance in the selection and preparation of suitable formulæ.—*Charleston Med. Journ. and Review*, Jan. 1858.

BY THE SAME AUTHOR. (*A new Edition.*)

NEW REMEDIES, WITH FORMULÆ FOR THEIR PREPARATION AND ADMINISTRATION. Seventh edition, with extensive Additions. In one very large octavo volume, leather, of 770 pages. \$3 75.

Another edition of the "New Remedies" having been called for, the author has endeavored to add everything of moment that has appeared since the publication of the last edition.

The articles treated of in the former editions will be found to have undergone considerable expansion in this, in order that the author might be enabled to introduce, as far as practicable, the results of the subsequent experience of others, as well as of his own observation and reflection; and to make the work still more deserving of the extended circulation with which the preceding editions have been favored by the profession. By an enlargement of the page, the numerous additions have been incorporated without greatly increasing the bulk of the volume.—*Preface*.

One of the most useful of the author's works.—*Southern Medical and Surgical Journal*.

This elaborate and useful volume should be found in every medical library, for as a book of reference, for physicians, it is unsurpassed by any other work in existence, and the double index for diseases and for remedies, will be found greatly to enhance its value.—*New York Med. Gazette*.

The great learning of the author, and his remarkable industry in pushing his researches into every source whence information is derivable, have enabled him to throw together an extensive mass of facts and statements, accompanied by full reference to authorities; which last feature renders the work practically valuable to investigators who desire to examine the original papers.—*The American Journal of Pharmacy*.

ELLIS (BENJAMIN), M. D.

THE MEDICAL FORMULARY: being a Collection of Prescriptions, derived from the writings and practice of many of the most eminent physicians of America and Europe. Together with the usual Dietetic Preparations and Antidotes for Poisons. To which is added an Appendix, on the Endermic use of Medicines, and on the use of Ether and Chloroform. The whole accompanied with a few brief Pharmacæutic and Medical Observations. Eleventh editor, revised and much extended by ROBERT P. THOMAS, M. D., Professor of Materia Medica in the Philadelphia College of Pharmacy. (*Preparing.*)

ERICHSEN (JOHN),

Professor of Surgery in University College, London, &c.

THE SCIENCE AND ART OF SURGERY; BEING A TREATISE ON SURGICAL

INJURIES, DISEASES, AND OPERATIONS. New and improved American, from the second enlarged and carefully revised London edition. Illustrated with over four hundred engravings on wood. In one large and handsome octavo volume, of one thousand closely printed pages, leather, raised bands. \$4 50. (*Just Issued.*)

The very distinguished favor with which this work has been received on both sides of the Atlantic has stimulated the author to render it even more worthy of the position which it has so rapidly attained as a standard authority. Every portion has been carefully revised, numerous additions have been made, and the most watchful care has been exercised to render it a complete exponent of the most advanced condition of surgical science. In this manner the work has been enlarged by about a hundred pages, while the series of engravings has been increased by more than a hundred, rendering it one of the most thoroughly illustrated volumes before the profession. The additions of the author having rendered unnecessary most of the notes of the former American editor, but little has been added in this country; some few notes and occasional illustrations have, however, been introduced to elucidate American modes of practice.

It is, in our humble judgment, decidedly the best book of the kind in the English language. Strange that just such books are not oftener produced by public teachers of surgery in this country and Great Britain. Indeed, it is a matter of great astonishment, but no less true than astonishing, that of the many works on surgery republished in this country within the last fifteen or twenty years as text-books for medical students, this is the only one that even approximates to the fulfillment of the peculiar wants of young men just entering upon the study of this branch of the profession.—*Western Jour. of Med. and Surgery.*

Its value is greatly enhanced by a very copious well-arranged index. We regard this as one of the most valuable contributions to modern surgery. To one entering his novitiate of practice, we regard it the most serviceable guide which he can consult. He will find a fulness of detail leading him through every

step of the operation, and not deserting him until the final issue of the case is decided.—*Sethosope.*

Embracing, as will be perceived, the whole surgical domain, and each division of itself almost complete and perfect, each chapter full and explicit, each subject faithfully exhibited, we can only express our estimate of it in the aggregate. We consider it an excellent contribution to surgery, as probably the best single volume now extant on the subject, and with great pleasure we add it to our text-books.—*Nashville Journal of Medicine and Surgery.*

Prof. Erichsen's work, for its size, has not been surpassed; his nine hundred and eight pages, profusely illustrated, are rich in physiological, pathological, and operative suggestions, doctrines, details, and processes; and will prove a reliable resource for information, both to physician and surgeon, in the hour of peril.—*N. O. Med. and Surg. Journal.*

FLINT (AUSTIN), M. D.,

Professor of the Theory and Practice of Medicine in the University of Louisville, &c.

PHYSICAL EXPLORATION AND DIAGNOSIS OF DISEASES AFFECTING THE RESPIRATORY ORGANS.

In one large and handsome octavo volume, extra cloth, 636 pages. \$3 00.

We regard it, in point both of arrangement and of the marked ability of its treatment of the subjects, as destined to take the first rank in works of this class. So far as our information extends, it has at present no equal. To the practitioner, as well as the student, it will be invaluable in clearing up the diagnosis of doubtful cases, and in shedding light upon difficult phenomena.—*Buffalo Med. Journal.*

A work of original observation of the highest merit. We recommend the treatise to every one who wishes to become a correct auscultator. Based to a very large extent upon cases numerically examined, it carries the evidence of careful study and discrimination upon every page. * It does credit to the author, and, through him, to the profession in this country. It is, what we cannot call every book upon auscultation, a readable book.—*Am. Jour. Med. Sciences.*

BY THE SAME AUTHOR. (*Now Ready.*)**A PRACTICAL TREATISE ON THE DIAGNOSIS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART.**

In one neat octavo volume, of about 500 pages, extra cloth. \$2 75.

We do not know that Dr. Flint has written anything which is not first rate; but this, his latest contribution to medical literature, in our opinion, surpasses all the others. The work is most comprehensive in its scope, and most sound in the views it enunciates. The descriptions are clear and methodical; the statements are substantiated by facts, and are made with such simplicity and sincerity, that without them they would carry conviction. The style is admirably clear, direct, and free from dryness. With Dr. Walshe's excellent treatise before us, we have no hesitation in saying that Dr. Flint's book is the best work on the heart in the English language.—*Boston Med. and Surg. Journal.*

We have thus endeavored to present our readers with a fair analysis of this remarkable work. Preferring to employ the very words of the distinguished author, wherever it was possible, we have essayed to condense into the briefest space a general view of his observations and suggestions, and to direct the attention of our brethren to the abounding stores of valuable matter here collected and arranged for their use and instruction. No medical library will hereafter be considered complete without this volume; and we trust it will promptly find its way into the hands of every American student and physician.—*N. Am. Med. Chir. Review.*

This last work of Prof. Flint will add much to his previous well-earned celebrity, as a writer of

great force and beauty, and, with his previous work, places him at the head of American writers upon diseases of the chest. We have adopted his work upon the heart as a text-book, believing it to be more valuable for that purpose than any work of the kind that has yet appeared.—*Nashville Med. Journ.*

With more than pleasure do we hail the advent of this work, for it fills a wide gap on the list of text-books for our schools, and is, for the practitioner, the most valuable practical work of its kind.—*N. O. Med. News.*

In regard to the merits of the work, we have no hesitation in pronouncing it full, accurate, and judicious. Considering the present state of science, such a work was much needed. It should be in the hands of every practitioner.—*Chicago Med. Journal.*

But these are very trivial spots, and in no wise prevent us from declaring our most hearty approval of the author's ability, industry, and conscientiousness.—*Dublin Quarterly Journal of Med. Sciences.*

He has labored on with the same industry and care, and his place among the first authors of our country is becoming fully established. To this end, the work whose title is given above, contributes in no small degree. Our space will not admit of an extended analysis, and we will close this brief notice by commending it without reserve to every class of readers in the profession.—*Peninsular Med. Journ.*

FOWNES (GEORGE), PH. D., &c.

A MANUAL OF ELEMENTARY CHEMISTRY; Theoretical and Practical.

From the seventh revised and corrected London edition. With one hundred and ninety-seven illustrations. Edited by ROBERT BRIDGES, M. D. In one large royal 12mo volume, of 600 pages. In leather, \$1 65; extra cloth, \$1 50. (*Just Issued.*)

The death of the author having placed the editorial care of this work in the practised hands of Drs. Bence Jones and A. W. Hoffman, everything has been done in its revision which experience could suggest to keep it on a level with the rapid advance of chemical science. The additions requisite to this purpose have necessitated an enlargement of the page, notwithstanding which the work has been increased by about fifty pages. At the same time every care has been used to maintain its distinctive character as a condensed manual for the student, divested of all unnecessary detail or mere theoretical speculation. The additions have, of course, been mainly in the department of Organic Chemistry, which has made such rapid progress within the last few years, but yet equal attention has been bestowed on the other branches of the subject—Chemical Physics and Inorganic Chemistry—to present all investigations and discoveries of importance, and to keep up the reputation of the volume as a complete manual of the whole science, admirably adapted for the learner. By the use of a small but exceedingly clear type the matter of a large octavo is compressed within the convenient and portable limits of a moderate sized duodecimo, and at the very low price affixed, it is offered as one of the cheapest volumes before the profession.

Dr. Fownes' excellent work has been universally recognized everywhere in his own and this country, as the best elementary treatise on chemistry in the English tongue, and is very generally adopted, we believe, as the standard text-book in all our colleges, both literary and scientific.—*Charleston Med Journ. and Review.*

A standard manual, which has long enjoyed the reputation of embodying much knowledge in a small space. The author has achieved the difficult task of condensation with mastery tact. His book is concise without being dry, and brief without being too dogmatical or general.—*Virginia Med. and Surgical Journal.*

The work of Dr. Fownes has long been before the public, and its merits have been fully appreciated as the best text-book on chemistry now in existence. We do not, of course, place it in a rank superior to the works of Brande, Graham, Turner, Gregory, or Gmelin, but we say that, as a work for students, it is preferable to any of them.—*London Journal of Medicine.*

A work well adapted to the wants of the student. It is an excellent exposition of the chief doctrines and facts of modern chemistry. The size of the work, and still more the condensed yet perspicuous style in which it is written, absolve it from the charges very properly urged against most manuals termed popular.—*Edinburgh Journal of Medical Science.*

FISKE FUND PRIZE ESSAYS.—THE EFFECTS OF CLIMATE ON TUBERCULOUS DISEASE. By EDWIN LEE, M. R. C. S., London, and **THE INFLUENCE OF PREGNANCY ON THE DEVELOPMENT OF TUBERCLES.** By

EDWARD WARREN, M. D., of Edenton, N. C. Together in one neat 8vo volume, extra cloth. \$1 00. **FRICK ON RENAL AFFECTIONS;** their Diagnosis and Pathology. With illustrations. One volume, royal 12mo., extra cloth. 75 cents

FERGUSON (WILLIAM), F. R. S.,
Professor of Surgery in King's College, London, &c.

A SYSTEM OF PRACTICAL SURGERY. Fourth American, from the third and enlarged London edition. In one large and beautifully printed octavo volume, of about 700 pages, with 393 handsome illustrations, leather. \$3 00.

GRAHAM (THOMAS), F. R. S.

THE ELEMENTS OF INORGANIC CHEMISTRY, including the Applications of the Science in the Arts. New and much enlarged edition, by HENRY WATTS and ROBERT BRIDGES, M. D. Complete in one large and handsome octavo volume, of over 800 very large pages, with two hundred and thirty-two wood-cuts, extra cloth. \$4 00.

* * Part II., completing the work from p. 431 to end, with Index, Title Matter, &c., may be had separate, cloth backs and paper sides. Price \$2 50.

From Prof. E. N. Horsford. *Harvard College.*

It has, in its earlier and less perfected editions, been familiar to me, and the excellence of its plan and the clearness and completeness of its discussions, have long been my admiration.

No reader of English works on this science can

afford to be without this edition of Prof. Graham's Elements.—*Silliman's Journal*, March, 1858.

From Prof. Wolcott Gibbs, N. Y. *Free Academy.*

The work is an admirable one in all respects, and its republication here cannot fail to exert a positive influence upon the progress of science in this country.

GRIFFITH (ROBERT E.), M. D., &c.

A UNIVERSAL FORMULARY, containing the methods of Preparing and Administering Official and other Medicines. The whole adapted to Physicians and Pharmacentists. **SECOND EDITION,** thoroughly revised, with numerous additions, by ROBERT P. THOMAS, M. D., Professor of Materia Medica in the Philadelphia College of Pharmacy. In one large and handsome octavo volume, extra cloth, of 650 pages, double columns. \$3 00; or in sheep, \$3 25.

It was a work requiring much perseverance, and when published was looked upon as by far the best work of its kind that had issued from the American press. Prof. Thomas has certainly "improved," as well as added to this Formulary, and has rendered it additionally deserving of the confidence of pharmacentists and physicians.—*Am. Journal of Pharmacy.*

We are happy to announce a new and improved edition of this one of the most valuable and useful works that have emanated from an American pen. It would do credit to any country, and will be found of daily usefulness to practitioners of medicine; it is better adapted to their purposes than the dispensatories.—*Southern Med. and Surg. Journal.*

It is one of the most useful books a country practitioner can possibly have.—*Medical Chronicle.*

This is a work of six hundred and fifty-one pages, embracing all on the subject of preparing and administering medicines that can be desired by the physician and pharmacist.—*Western Lancet.*

The amount of useful, every-day matter for a practicing physician, is really immense.—*Boston Med. and Surg. Journal.*

This edition has been greatly improved by the revision and ample additions of Dr. Thomas, and is now, we believe, one of the most complete works of its kind in any language. The additions amount to about seventy pages, and no effort has been spared to include in them all the recent improvements. A work of this kind appears to us indispensable to the physician, and there is none we can more cordially recommend. *N Y Journal of Medicine.*

GROSS (SAMUEL D.), M. D.,

Professor of Surgery in the Jefferson Medical College of Philadelphia, &c.

Enlarged Edition—Now Ready, January, 1862.

A SYSTEM OF SURGERY: Pathological, Diagnostic, Therapeutic, and Operative. Illustrated by TWELVE HUNDRED AND TWENTY-SEVEN ENGRAVINGS. Second edition, much enlarged and carefully revised. In two large and beautifully printed octavo volumes, of about twenty-two hundred pages; strongly bound in leather, with raised bands. Price \$12.

The exhaustion in little more than two years of a large edition of so elaborate and comprehensive a work as this is the best evidence that the author was not mistaken in his estimate of the want which existed of a complete American System of Surgery, presenting the science in all its necessary details and in all its branches. That he has succeeded in the attempt to supply this want is shown not only by the rapid sale of the work, but also by the very favorable manner in which it has been received by the organs of the profession in this country and in Europe, and by the fact that a translation is now preparing in Holland—a mark of appreciation not often bestowed on any scientific work so extended in size.

The author has not been insensible to the kindness thus bestowed upon his labors, and in revising the work for a new edition he has spared no pains to render it worthy of the favor with which it has been received. Every portion has been subjected to close examination and revision; any deficiencies apparent have been supplied, and the results of recent progress in the science and art of surgery have been everywhere introduced; while the series of illustrations has been enlarged by the addition of nearly three hundred wood-cuts, rendering it one of the most thoroughly illustrated works ever laid before the profession. To accommodate these very extensive additions, the work has been printed upon a smaller type, so that notwithstanding the very large increase in the matter and value of the book, its size is more convenient and less cumbersome than before. Every care has been taken in the printing to render the typographical execution unexceptionable, and it is confidently presented as a work in every way worthy of a place in even the most limited library of the practitioner or student.

A few testimonials of the value of the former edition are appended.

Has Dr. Gross satisfactorily fulfilled this object? A careful perusal of his volumes enables us to give an answer in the affirmative. Not only has he given to the reader an elaborate and well-written account of his own vast experience, but he has not failed to embody in his pages the opinions and practice of surgeons in this and other countries of Europe. The result has been a work of such completeness, that it has no superior in the systematic treatises on surgery which have emanated from English or Continental authors. It has been justly objected that these have been far from complete in many essential particulars, many of them having been deficient in some of the most important points which should characterize such works. Some of them have been elaborate—too elaborate—with respect to certain diseases, while they have merely glanced at, or given an unsatisfactory account of, others equally important to the surgeon. Dr. Gross has avoided this error, and has produced the most complete work that has yet issued from the press on the science and practice of surgery. It is not, strictly speaking, a Dictionary of Surgery, but it gives to the reader all the information that he may require for his treatment of surgical diseases. Having said so much, it might appear superfluous to add another word; but it is only due to Dr. Gross to state that he has embraced the opportunity of transferring to his pages a vast number of engravings from English and other authors, illustrative of the pathology and treatment of surgical diseases. To these are added several hundred original wood-cuts. The work altogether commends itself to the attention of British surgeons, from whom it cannot fail to meet with extensive patronage.—*London Lancet*, Sept. 1, 1860.

Of Dr. Gross's treatise on Surgery we can say no more than that it is the most elaborate and complete work on this branch of the healing art which has ever been published in any country. A systematic work, it admits of no analytical review; but, did our space permit, we should gladly give some extracts from it, to enable our readers to judge of the classical style of the author, and the exhausting way in which each subject is treated.—*Dublin Quarterly Journal of Med. Science*.

The work is so superior to its predecessors in matter and extent, as well as in illustrations and style of publication, that we can honestly recommend it as the best work of the kind to be taken home by the young practitioner.—*Am. Med. Journ.*

With pleasure we record the completion of this long-anticipated work. The reputation which the author has for many years sustained, both as a surgeon and as a writer, had prepared us to expect a treatise of great excellence and originality; but we confess we were by no means prepared for the work which is before us—the most complete treatise upon surgery ever published, either in this or any other country, and we might, perhaps, safely say, the most original. There is no subject belonging properly to surgery which has not received from the author a due share of attention. Dr. Gross has supplied a want in surgical literature which has long been felt by practitioners; he has furnished us with a complete practical treatise upon surgery in all its departments. As Americans, we are proud of the achievement; as surgeons, we are most sincerely thankful to him for his extraordinary labors in our behalf.—*N. Y. Monthly Review and Buffalo Med. Journal*.

BY THE SAME AUTHOR.

ELEMENTS OF PATHOLOGICAL ANATOMY. Third edition, thoroughly revised and greatly improved. In one large and very handsome octavo volume, with about three hundred and fifty beautiful illustrations, of which a large number are from original drawings. Price in extra cloth, \$4 75; leather, raised bands, \$5 25. (*Lately Published.*)

The very rapid advances in the Science of Pathological Anatomy during the last few years have rendered essential a thorough modification of this work, with a view of making it a correct exponent of the present state of the subject. The very careful manner in which this task has been executed, and the amount of alteration which it has undergone, have enabled the author to say that "with the many changes and improvements now introduced, the work may be regarded almost as a new treatise," while the efforts of the author have been seconded as regards the mechanical execution of the volume, rendering it one of the handsomest productions of the American press.

We most sincerely congratulate the author on the successful manner in which he has accomplished his proposed object. His book is most admirably calculated to fill up a blank which has long been felt to exist in this department of medical literature, and as such must become very widely circulated amongst all classes of the profession.—*Dublin Quarterly Journal of Med. Science*, Nov. 1857.

We have been favorably impressed with the general manner in which Dr. Gross has executed his task of affording a comprehensive digest of the present state of the literature of Pathological Anatomy, and have much pleasure in recommending his work to our readers, as we believe one well deserving of diligent perusal and careful study.—*Montreal Med. Chron.*, Sept. 1857.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON FOREIGN BODIES IN THE AIR-PAS-SAGES. In one handsome octavo volume, extra cloth, with illustrations. pp. 468. \$2 75.

GROSS (SAMUEL D.), M. D.,

Professor of Surgery in the Jefferson Medical College of Philadelphia, &c.

A PRACTICAL TREATISE ON THE DISEASES, INJURIES, AND MALFORMATIONS OF THE URINARY BLADDER, THE PROSTATE GLAND, AND THE URETHRA. Second Edition, revised and much enlarged, with one hundred and eighty-four illustrations. In one large and very handsome octavo volume, of over nine hundred pages. In leather, raised bands, \$5 25; extra cloth, \$4 75.

Philosophical in its design, methodical in its arrangement, ample and sound in its practical details, it may in truth be said to leave scarcely anything to be desired on so important a subject.—*Boston Med. and Surg. Journal*.

Whoever will peruse the vast amount of valuable practical information it contains, will, we think,

agree with us, that there is no work in the English language which can make any just pretensions to be its equal.—*N. Y. Journal of Medicine*.

A volume replete with truths and principles of the utmost value in the investigation of these diseases.—*American Medical Journal*.

GRAY (HENRY), F. R. S.,

Lecturer on Anatomy at St. George's Hospital, London, &c.

ANATOMY, DESCRIPTIVE AND SURGICAL. The Drawings by H. V.

CARTER, M. D., late Demonstrator on Anatomy at St. George's Hospital; the Dissections jointly by the AUTHOR and Dr. CARTER. Second American, from the second revised and improved London edition. In one magnificent imperial octavo volume, of over 800 pages, with 388 large and elaborate engravings on wood. Price in extra cloth, \$6 25; leather, raised bands, \$7 00. (Now Ready, 1862.)

The speedy exhaustion of a large edition of this work is sufficient evidence that its plan and execution have been found to present superior practical advantages in facilitating the study of Anatomy. In presenting it to the profession a second time, the author has availed himself of the opportunity to supply any deficiencies which experience in its use had shown to exist, and to correct any errors of detail, to which the first edition of a scientific work on so extensive and complicated a science is liable. These improvements have resulted in some increase in the size of the volume, while twenty-six new wood-cuts have been added to the beautiful series of illustrations which form so distinctive a feature of the work. The American edition has been passed through the press under the supervision of a competent professional man, who has taken every care to render it in all respects accurate, and it is now presented, without any increase of price, as fitted to maintain and extend the popularity which it has everywhere acquired.

With little trouble, the busy practitioner whose knowledge of anatomy may have become obscured by want of practice, may now resuscitate his former anatomical lore, and be ready for any emergency. It is to this class of individuals, and not to the student alone, that this work will ultimately tend to be of most incalculable advantage, and we feel satisfied that the library of the medical man will soon be considered incomplete in which a copy of this work does not exist.—*Madras Quarterly Journal of Med. Science*, July, 1861.

This edition is much improved and enlarged, and contains several new illustrations by Dr. Westmacott. The volume is a complete companion to the dissecting-room, and saves the necessity of the student possessing a variety of "Manuals."—*The London Lancet*, Feb. 9, 1861.

The work before us is one entitled to the highest praise, and we accordingly welcome it as a valuable addition to medical literature. Intermediate in fulness of detail between the treatises of Saarep and of Wilson, its characteristic merit lies in the number and excellence of the engravings it contains. Most of these are original, of much larger than ordinary size, and admirably executed. The various parts are also lettered after the plan adopted in Holden's Osteology. It would be difficult to over-estimate the advantages offered by this mode of pictorial illustration. Bones, ligaments, muscles, bloodvessels, and nerves are each in turn figured, and marked with their appropriate names; thus enabling the student to comprehend, at a glance, what would otherwise often be ignored, or at any rate, acquired only by prolonged and tiresome application. In conclusion, we heartily commend the work of Mr. Gray to the attention of the medical profession, feeling certain that it should be regarded as one of the most valuable contributions ever made to educational literature.—*N. Y. Monthly Review*. Dec. 1859.

In this view, we regard the work of Mr. Gray as far better adapted to the wants of the profession, and especially of the student, than any treatise on anatomy yet published in this country. It is destined, we believe, to supersede all others, both as a manual of dissections, and a standard of reference to the student of general or relative anatomy.—*N. Y. Journal of Medicine*, Nov. 1859.

For this truly admirable work the profession is indebted to the distinguished author of "Gray on the Spleen." The vacancy it fills has been long felt

to exist in this country. Mr. Gray writes throughout with both branches of his subject in view. His description of each particular part is followed by a notice of its relations to the parts with which it is connected, and this, too, sufficiently ample for all the purposes of the operative surgeon. After describing the bones and muscles, he gives a concise statement of the fractures to which the bones of the extremities are most liable, together with the amount and direction of the displacement to which the fragments are subjected by muscular action. The section on arteries is remarkably full and accurate. Not only is the surgical anatomy given to every important vessel, with directions for its ligation, but at the end of the description of each arterial trunk we have a useful summary of the irregularities which may occur in its origin, course, and termination.—*N. A. Med. Chir. Review*, Mar. 1859.

Mr. Gray's book, in excellence of arrangement and completeness of execution, exceeds any work on anatomy hitherto published in the English language, affording a complete view of the structure of the human body, with especial reference to practical surgery. Thus the volume constitutes a perfect book of reference for the practitioner, demanding a place in even the most limited library of the physician or surgeon, and a work of necessity for the student to fix in his mind what he has learned by the dissecting knife from the book of nature.—*The Dublin Quarterly Journal of Med. Sciences*, Nov. 1858.

In our judgment, the mode of illustration adopted in the present volume cannot but present many advantages to the student of anatomy. To the zealous disciple of Vesalius, earnestly desirous of real improvement, the book will certainly be of immense value; but, at the same time, we must also confess that to those simply desirous of "cranning" it will be an undoubted godsend. The peculiar value of Mr. Gray's mode of illustration is nowhere more markedly evident than in the chapter on osteology, and especially in those portions which treat of the bones of the head and of their development. The study of these parts is thus made one of comparative ease, if not of positive pleasure; and those bugbears of the student, the temporal and sphenoid bones, are shorn of half their terrors. It is, in our estimation, an admirable and complete text-book for the student, and a useful work of reference for the practitioner; its pictorial character forming a novel element, to which we have already sufficiently alluded.—*Am. Journ. Med. Sci.*, July, 1859.

GIBSON'S INSTITUTES AND PRACTICE OF SURGERY. Eighth edition, improved and altered. With thirty-four plates. In two handsome octavo volumes, containing about 1,000 pages, leather, raised hand. \$6 50.

GARDNER'S MEDICAL CHEMISTRY, for the use of Students and the Profession. In one royal 12mo. vol., cloth, pp. 396, with wood-cuts. \$1.

GLUGE'S ATLAS OF PATHOLOGICAL HISTOLOGY. Translated, with Notes and Addi-

tions by JOSEPH LEIDY, M. D. In one volume, very large imperial quarto, extra cloth, with 320 copper plate figures, plain and colored, \$5 00.

HUGHES' INTRODUCTION TO THE PRACTICE OF AUSCULTATION AND OTHER MODES OF PHYSICAL DIAGNOSIS. IN DISEASES OF THE LUNGS AND HEART. Second edition. 1 vol. royal 12mo., ex. cloth, pp. 304. \$1 00.

HAMILTON (FRANK H.), M. D.,

Professor of Surgery in the Long Island College Hospital.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS. In one large and handsome octavo volume, of over 750 pages, with 289 illustrations. \$4 25. (*Now Ready, January, 1860.*)

Among the many good workers at surgery of whom America may now boast not the least is Frank Hamilton; and the volume before us is what we say it with a pang of wounded patriotism the best and handiest book on the subject in the English language. It is in vain to attempt a review of it; nearly as vain to seek for any sins, either of commission or omission. We have seen no work on practical surgery which we would sooner recommend to our brother surgeons, especially those of "the services," or those whose practice lies in districts where a man has necessarily to rely on his own unaided resources. The practitioner will find in it directions for nearly every possible accident, easily found and comprehended; and much pleasant reading for him to muse over in the after consideration of his cases. — *Edinburgh Med. Journ.* Feb 1861.

This is a valuable contribution to the surgery of most important affections, and is the more welcome, inasmuch as at the present time we do not possess a single complete treatise on Fractures and Dislocations in the English language. It has remained for our American brother to produce a complete treatise upon the subject, and bring together in a convenient form those alterations and improvements that have been made from time to time in the treatment of these affections. One great and valuable feature in the work before us is the fact that it comprises all the improvements introduced into the practice of both English and American surgery, and though far from omitting mention of our continental neighbors, the author by no means encourages the notion—but too prevalent in some quarters—that nothing is good unless imported from France or Germany. The latter half of the work is devoted to the consideration of the various dislocations and their appropriate treatment, and its merit is fully equal to that of the preceding portion. — *The London Lancet*, May 5, 1860.

It is emphatically the book upon the subjects of which it treats, and we cannot doubt that it will continue so to be for an indefinite period of time. When we say, however, that we believe it will at once take its place as the best book for consultation by the practitioner; and that it will form the most complete, available, and reliable guide in emergencies of every nature connected with its subjects; and also that the student of surgery may make it his textbook with entire confidence, and with pleasure also, from its agreeable and easy style—we think our own

opinion may be gathered as to its value. — *Boston Medical and Surgical Journal*, March 1, 1860.

The work is concise, judicious, and accurate, and adapted to the wants of the student, practitioner, and investigator, honorable to the author and to the profession. — *Chicago Med. Journal*, March, 1860.

We regard this work as an honor not only to its author, but to the profession of our country. Were we to review it thoroughly, we could not convey to the mind of the reader more forcibly our honest opinion expressed in the few words—we think it the best book of its kind extant. Every man interested in surgery will soon have this work on his desk. He who does not, will be the loser. — *New Orleans Medical News*, March, 1860.

Now that it is before us, we feel bound to say that much as was expected from it, and onerous as was the undertaking, it has surpassed expectation, and achieved more than was pledged in its behalf; for its title does not express in full the richness of its contents. On the whole, we are prouder of this work than of any which has for years emanated from the American medical press; its sale will certainly be very large in this country, and we anticipate its eliciting much attention in Europe. — *Nashville Medical Record*, Mar. 1860.

Every surgeon, young and old, should possess himself of it, and give it a careful perusal, in doing which he will be richly repaid. — *St. Louis Med. and Surg. Journal*, March, 1860.

Dr. Hamilton is fortunate in having succeeded in filling the void, so long felt, with what cannot fail to be at once accepted as a model monograph in some respects, and a work of classical authority. We sincerely congratulate the profession of the United States on the appearance of such a publication from one of their number. We have reason to be proud of it as an original work, both in a literary and a scientific point of view, and to esteem it as a valuable guide in a most difficult and important branch of study and practice. On every account, therefore, we hope that it may soon be widely known abroad as an evidence of genuine progress on this side of the Atlantic, and further, that it may be still more widely known at home as an authoritative teacher from which every one may profitably learn, and as affording an example of honest, well-directed, and untiring industry in authorship which every surgeon may emulate. — *Am. Med. Journal*, April, 1860.

HOBLYN (RICHARD D.), M. D.

A DICTIONARY OF THE TERMS USED IN MEDICINE AND THE COLLATERAL SCIENCES. A new American edition. Revised, with numerous Additions, by ISAAC HAYS, M. D., editor of the "American Journal of the Medical Sciences." In one large royal 12mo. volume, leather, of over 500 double columned pages. \$1 50.

To both practitioner and student, we recommend this dictionary as being convenient in size, accurate in definition, and sufficiently full and complete for ordinary consultation. — *Charleston Med. Journ.*

We know of no dictionary better arranged and adapted. It is not encumbered with the obsolete terms of a bygone age, but it contains all that are now in

use; embracing every department of medical science down to the very latest date. — *Western Lancet*.

Hoblyn's Dictionary has long been a favorite with us. It is the best book of definitions we have, and ought always to be upon the student's table. — *Southern Med. and Surg. Journal*.

HOLLAND'S MEDICAL NOTES AND REFLECTIONS. From the third London edition.

In one handsome octavo volume, extra cloth. \$3.

HORNER'S SPECIAL ANATOMY AND HIS-

TOLOGY. Eighth edition. Extensively revised and modified. In two large octavo volumes, extra cloth, of more than 1000 pages, with over 300 illustrations. \$6 00.

HODGE (HUGH L.), M. D.,

Professor of Midwifery and the Diseases of Women and Children in the University of Pennsylvania, &c.

ON DISEASES PECULIAR TO WOMEN, including Displacements of the Uterus. With original illustrations. In one beautifully printed octavo volume, of nearly 500 pages, extra cloth. \$3 25. (*Now Ready.*)

We will say at once that the work fulfils its object capitally well; and we will moreover venture the assertion that it will inaugurate an improved practice throughout this whole country. The secrets of the author's success are so clearly revealed that the attentive student cannot fail to insure a goodly portion of similar success in his own practice. It is a credit to *all* medical literature; and we add, that the physician who does not place it in his library, and who does not faithfully con its pages, will lose a vast deal of knowledge that would be most useful to himself and beneficial to his patients. *It is a practical work of the highest order of merit; and it will take rank as such immediately.*—*Maryland and Virginia Medical Journal*, Feb. 1861.

This contribution towards the elucidation of the pathology and treatment of some of the diseases peculiar to women, cannot fail to meet with a favorable reception from the medical profession. The character of the particular maladies of which the work before us treats; their frequency, variety, and obscenity; the amount of malaise and even of actual suffering by which they are invariably attended; their obstinacy, the difficulty with which they are overcome, and their disposition again and again to recur—these, taken in connection with the entire competency of the author to render a correct account of their nature, their causes, and their appro-

priate management—his ample experience, his matured judgment, and his perfect conscientiousness—invest this publication with an interest and value to which few of the medical treatises of a recent date can lay a stronger, if, perchance, an equal claim.—*Am. Journ. Med. Sciences*, Jan. 1861.

Indeed, although no part of the volume is not eminently deserving of perusal and study, we think that the nine chapters devoted to this subject, are especially so, and we know of no more valuable monograph upon the symptoms, prognosis, and management of these annoying maladies than is constituted by this part of the work. We cannot but regard it as one of the most original and most practical works of the day; one which every accoucheur and physician should most carefully read; for we are persuaded that he will arise from its perusal with new ideas, which will induct him into a more rational practice in regard to many a suffering female, who may have placed her health in his hands.—*British American Journal*, Feb. 1861.

Of the many excellences of the work we will not speak at length. We advise all who would acquire a knowledge of the proper management of the maladies of which it treats, to study it with care. The second part is of itself a most valuable contribution to the practice of our art.—*Am. Med. Monthly and New York Review*, Feb. 1861.

The illustrations, which are all original, are drawn to a uniform scale of one-half the natural size.

HABERSHON (S. O.), M. D.,

Assistant Physician to and Lecturer on Materia Medica and Therapeutics at Guy's Hospital, &c.

PATHOLOGICAL AND PRACTICAL OBSERVATIONS ON DISEASES OF THE ALIMENTARY CANAL, OESOPHAGUS, STOMACH, CÆCUM, AND INTES-TINES. With illustrations on wood. In one handsome octavo volume of 312 pages, extra cloth \$1 75. (*Now Ready.*)

JONES (T. WHARTON), F. R. S.,

Professor of Ophthalmic Medicine and Surgery in University College, London, &c.

THE PRINCIPLES AND PRACTICE OF OPHTHALMIC MEDICINE AND SURGERY. With one hundred and ten illustrations. Second American from the second and revised London edition, with additions by EDWARD HARTSHORNE, M. D., Surgeon to Wills' Hospital, &c. In one large, handsome royal 12mo. volume, extra cloth, of 500 pages. \$1 50.

JONES (C. HANDFIELD), F. R. S., & EDWARD H. SIEVEKING, M. D.,
Assistant Physicians and Lecturers in St. Mary's Hospital, London.

A MANUAL OF PATHOLOGICAL ANATOMY. First American Edition, Revised. With three hundred and ninety-seven handsome wood engravings. In one large and beautiful octavo volume of nearly 750 pages, leather. \$3 75.

As a concise text-book, containing, in a condensed form, a complete outline of what is known in the domain of Pathological Anatomy, it is perhaps the best work in the English language. Its great merit consists in its completeness and brevity, and in this respect it supplies a great desideratum in our literature. Heretofore the student of pathology was

obliged to glean from a great number of monographs, and the field was so extensive that but few cultivated it with any degree of success. As a simple work of reference, therefore, it is of great value to the student of pathological anatomy, and should be in every physician's library.—*Western Lancet*.

KIRKES (WILLIAM SENHOUSE), M. D.,

Demonstrator of Morbid Anatomy at St. Bartholomew's Hospital, &c.

A MANUAL OF PHYSIOLOGY. A new American, from the third and improved London edition. With two hundred illustrations. In one large and handsome royal 12mo. volume, leather. pp. 586. \$2 00. (*Lately Published.*)

This is a new and very much improved edition of Dr. Kirkes' well-known Handbook of Physiology. It combines conciseness with completeness, and is, therefore, admirably adapted for consultation by the busy practitioner.—*Dublin Quarterly Journal*.

One of the very best handbooks of Physiology we possess—presenting just such an outline of the science as the student requires during his attendance upon a course of lectures, or for reference whilst preparing for examination.—*Am. Medical Journal*

Its excellence is in its compactness, its clearness,

and its carefully cited authorities. It is the most convenient of text-books. These gentlemen, Messrs. Kirkes and Paget, have the gift of telling us what we want to know, without thinking it necessary to tell us all they know.—*Boston Med and Surg. Journal*.

For the student beginning this study, and the practitioner who has but leisure to refresh his memory, this book is invaluable, as it contains all that it is important to know.—*Charleston Med. Journal*.

KNAPP'S TECHNOLOGY; or, Chemistry applied to the Arts and to Manufactures. Edited by Dr. RONALDS, Dr. RICHARDSON, and Prof. W. R. JOHNSON. In two handsome 8vo. vols., without 500 wood-engravings. \$6 00.

LAYCOCK'S LECTURES ON THE PRINCIPLES AND METHODS OF MEDICAL OBSERVATION AND RESEARCH. For the Use of Advanced Students and Junior Practitioners. In one royal 12mo. volume, extra cloth. Price \$1.

LALLEMAND AND WILSON.

A PRACTICAL TREATISE ON THE CAUSES, SYMPTOMS, AND TREATMENT OF SPERMATORRHOEA. By M. LALLEMAND. Translated and edited by HENRY J. McDUGALL. Third American edition. To which is added — **ON DISEASES OF THE VESICULÆ SEMINALES; AND THEIR ASSOCIATED ORGANS.** With special reference to the Morbid Secretions of the Prostatic and Urethral Mucous Membrane. By MARRIS WILSON, M. D. In one neat octavo volume, of about 400 pp., extra cloth. \$2 00. (*Just Issued.*)

LA ROCHE (R.), M. D., &c.

YELLOW FEVER, considered in its Historical, Pathological, Etiological, and Therapeutical Relations. Including a Sketch of the Disease as it has occurred in Philadelphia from 1699 to 1854, with an examination of the connections between it and the fevers known under the same name in other parts of temperate as well as in tropical regions. In two large and handsome octavo volumes of nearly 1500 pages, extra cloth. \$7 00.

From Professor S. H. Dickson, Charleston, S. C., September 18, 1855.

A monument of intelligent and well applied research, almost without example. It is, indeed, in itself, a large library, and is destined to constitute the special resort as a book of reference, in the subject of which it treats, to all future time.

We have not time at present, engaged as we are, by day and by night, in the work of combating this very disease, now prevailing in our city, to do more than give this cursory notice of what we consider as undoubtedly the most able and erudite medical publication our country has yet produced. But in view of the startling fact, that this, the most malig-

nant and unmanageable disease of modern times, has for several years been prevailing in our country to a greater extent than ever before; that it is no longer confined to either large or small cities, but penetrates country villages, plantations, and farm-houses; that it is treated with scarcely better success now than thirty or forty years ago; that there is vast mischief done by ignorant pretenders to knowledge in regard to the disease, and in view of the probability that a majority of southern physicians will be called upon to treat the disease, we trust that this able and comprehensive treatise will be very generally read in the south.—*Memphis Med. Recorder.*

BY THE SAME AUTHOR.

PNEUMONIA; its Supposed Connection, Pathological and Etiological, with Autumnal Fevers, including an Inquiry into the Existence and Morbid Agency of Malaria. In one handsome octavo volume, extra cloth, of 500 pages. \$3 00.

LAWRENCE (W.), F. R. S., &c.

A TREATISE ON DISEASES OF THE EYE. A new edition, edited, with numerous additions, and 243 illustrations, by ISAAC HAYS, M. D., Surgeon to Will's Hospital, &c. In one very large and handsome octavo volume, of 950 pages, strongly bound in leather with raised bands. \$5 00.

LUDLOW (J. L.), M. D.

A MANUAL OF EXAMINATIONS upon Anatomy, Physiology, Surgery, Practice of Medicine, Obstetrics, Materia Medica, Chemistry, Pharmacy, and Therapeutics. To which is added a Medical Formulary. Third edition, thoroughly revised and greatly extended and enlarged. With 370 illustrations. In one handsome royal 12mo. volume, leather, of 816 large pages. \$2 50.

We know of no better companion for the student during the hours spent in the lecture room, or to refresh, at a glance, his memory of the various topics

crammed into his head by the various professors to whom he is compelled to listen.—*Western Lancet*, May, 1857.

LEHMANN (C. G.)

PHYSIOLOGICAL CHEMISTRY. Translated from the second edition by GEORGE E. DAY, M. D., F. R. S., &c., edited by R. E. ROGERS, M. D., Professor of Chemistry in the Medical Department of the University of Pennsylvania, with illustrations selected from Funke's Atlas of Physiological Chemistry, and an Appendix of plates. Complete in two large and handsome octavo volumes, extra cloth, containing 1200 pages, with nearly two hundred illustrations. \$6 00.

The work of Lehmann stands unrivalled as the most comprehensive book of reference and information extant on every branch of the subject on which it treats.—*Edinburgh Journal of Medical Science.*

The most important contribution as yet made to Physiological Chemistry.—*Am. Journal Med. Sciences*, Jan. 1856.

BY THE SAME AUTHOR. (*Lately Published.*)

MANUAL OF CHEMICAL PHYSIOLOGY. Translated from the German, with Notes and Additions, by J. CHESTON MORRIS, M. D., with an Introductory Essay on Vital Force, by Professor SAMUEL JACKSON, M. D., of the University of Pennsylvania. With illustrations on wood. In one very handsome octavo volume, extra cloth, of 336 pages. \$2 25.

From Prof. Jackson's Introductory Essay.

In adopting the handbook of Dr. Lehmann as a manual of Organic Chemistry for the use of the students of the University, and in recommending his original work of **PHYSIOLOGICAL CHEMISTRY** for their more mature studies, the high value of his researches, and the great weight of his authority in that important department of medical science are fully recognized.

LYONS (ROBERT D.), K. C. C.,

Late Pathologist in-chief to the British Army in the Crimea, &c.

A TREATISE ON FEVER; or, selections from a course of Lectures on Fever. Being part of a course of Theory and Practice of Medicine. In one neat octavo volume, of 362 pages, extra cloth; \$2 00. (*Now Ready.*)

From the Author's Preface.

"I am induced to publish this work on Fever with a view to bring within the reach of the student and junior practitioner, in a convenient form, the more recent results of inquiries into the Pathology and Therapeutics of this formidable class of diseases.

"The works of the great writers on Fever are so numerous, and in the present day are scattered in so many languages, that they are difficult of access, not only to students but also to practitioners. I shall deem myself fortunate if I can in any measure supply the want which is felt in this respect.

We have great pleasure in recommending Dr. Lyons' work on *Fever* to the attention of the profession. It is a work which cannot fail to enhance the author's previous well-earned reputation, as a diligent, careful, and accurate observer.—*British Med. Journal*, March 2, 1861.

Taken as a whole we can recommend it in the highest terms as well worthy the careful perusal and study of every student and practitioner of medi-

cine. We consider the work a most valuable addition to medical literature, and one destined to wield no little influence over the mind of the profession.—*Med. and Surg. Reporter*, May 4, 1861.

This is an admirable work upon the most remarkable and most important class of diseases to which mankind are liable.—*Med. Journ. of N. Carolina*, May, 1861.

MEIGS (CHARLES D.), M. D.,

Professor of Obstetrics, &c. in the Jefferson Medical College, Philadelphia.

OBSTETRICS: THE SCIENCE AND THE ART. Third edition, revised and improved. With one hundred and twenty-nine illustrations. In one beautifully printed octavo volume, leather, of seven hundred and fifty-two large pages. \$3 75.

Though the work has received only five pages of enlargement, its chapters throughout wear the impress of careful revision. Expunging and rewriting, remodelling its sentences, with occasional new material, all evince a lively desire that it shall deserve to be regarded as improved in *manner* as well as *matter*. In the *matter*, every stroke of the pen has increased the value of the book, both in expungings and additions.—*Western Lancet*, Jan. 1857.

The best American work on Midwifery that is accessible to the student and practitioner—*N. W. Med. and Surg. Journal*, Jan. 1857.

This is a standard work by a great American Obstetrician. It is the third and last edition, and, in the language of the preface, the author has "brought the subject up to the latest dates of real improvement in our art and Science."—*Nashville Journ. of Med. and Surg.*, May, 1857.

BY THE SAME AUTHOR. (*Just Issued.*)

WOMAN: HER DISEASES AND THEIR REMEDIES. A Series of Lectures to his Class. Fourth and Improved edition. In one large and beautifully printed octavo volume, leather, of over 700 pages. \$3 60.

In other respects, in our estimation, too much cannot be said in praise of this work. It abounds with beautiful passages, and for conciseness, for originality, and for all that is commendable in a work on the diseases of females, it is not excelled, and probably not equalled in the English language. On the whole, we know of no work on the diseases of women which we can so cordially commend to the student and practitioner as the one before us.—*Ohio Med. and Surg. Journal*.

The body of the book is worthy of attentive consideration, and is evidently the production of a clever, thoughtful, and sagacious physician. Dr. Meigs's letters on the diseases of the external organs, contain many interesting and rare cases, and many instructive observations. We take our leave of Dr. Meigs, with a high opinion of his talents and originality.—*The British and Foreign Medico-Chirurgical Review*.

Every chapter is replete with practical instruction, and bears the impress of being the composition of an acute and experienced mind. There is a terseness, and at the same time an accuracy in his description of symptoms, and in the rules for diagnosis,

which cannot fail to recommend the volume to the attention of the reader.—*Ranking's Abstract*.

It contains a vast amount of practical knowledge, by one who has accurately observed and retained the experience of many years.—*Dublin Quarterly Journal*.

Full of important matter, conveyed in a ready and agreeable manner.—*St. Louis Med. and Surg. Jour.*

There is an off-hand fervor, a glow, and a warm-heartedness infecting the effort of Dr. Meigs, which is entirely captivating, and which absolutely hurries the reader through from beginning to end. Besides, the book teems with solid instruction, and it shows the very highest evidence of ability, viz., the clearness with which the information is presented. We know of no better test of one's understanding a subject than the evidence of the power of lucidly explaining it. The most elementary, as well as the obscurest subjects, under the pencil of Prof. Meigs, are isolated and made to stand out in such bold relief, as to produce distinct impressions upon the mind and memory of the reader.—*The Charleston Med. Journal*.

BY THE SAME AUTHOR.

ON THE NATURE, SIGNS, AND TREATMENT OF CHILDBED FEVER. In a Series of Letters addressed to the Students of his Class. In one handsome octavo volume, extra cloth, of 365 pages. \$2 50.

The instructive and interesting author of this work, whose previous labors have placed his countrymen under deep and abiding obligations, again challenges their admiration in the fresh and vigorous, attractive and racy pages before us. It is a de-

lectable book. * * * This treatise upon childbed fevers will have an extensive sale, being destined, as it deserves, to find a place in the library of every practitioner who scorns to lag in the rear.—*Nashville Journal of Medicine and Surgery*.

BY THE SAME AUTHOR; WITH COLORED PLATES.

A TREATISE ON ACUTE AND CHRONIC DISEASES OF THE NECK OF THE UTERUS. With numerous plates, drawn and colored from nature in the highest style of art. In one handsome octavo volume, extra cloth. \$4 50.

MACLISE (JOSEPH), SURGEON.

SURGICAL ANATOMY. Forming one volume, very large imperial quarto.

With sixty-eight large and splendid Plates, drawn in the best style and beautifully colored. Containing one hundred and ninety Figures, many of them the size of life. Together with copious and explanatory letter-press. Strongly and handsomely bound in extra cloth, being one of the cheapest and best executed Surgical works as yet issued in this country. \$11 00.

*. * The size of this work prevents its transmission through the post-office as a whole, but those who desire to have copies forwarded by mail, can receive them in five parts, done up in stout wrappers. Price \$9 00.

One of the greatest artistic triumphs of the age in Surgical Anatomy.—*British American Medical Journal*.

No practitioner whose means will admit should fail to possess it.—*Ranking's Abstract*.

Too much cannot be said in its praise; indeed, we have not language to do it justice.—*Ohio Medical and Surgical Journal*.

The most accurately engraved and beautifully colored plates we have ever seen in an American book—one of the best and cheapest surgical works ever published.—*Buffalo Medical Journal*.

It is very rare that so elegantly printed, so well illustrated, and so useful a work, is offered at so moderate a price.—*Charleston Medical Journal*.

Its plates can boast a superiority which places them almost beyond the reach of competition.—*Medical Examiner*.

Country practitioners will find these plates of immense value.—*N. Y. Medical Gazette*.

A work which has no parallel in point of accuracy and cheapness in the English language.—*N. Y. Journal of Medicine*.

We are extremely gratified to announce to the profession the completion of this truly magnificent work, which, as a whole, certainly stands unrivalled, both for accuracy of drawing, beauty of coloring, and all the requisite explanations of the subject in hand.—*The New Orleans Medical and Surgical Journal*.

This is by far the ablest work on Surgical Anatomy that has come under our observation. We know of no other work that would justify a student, in any degree, for neglect of actual dissection. In those sudden emergencies that so often arise, and which require the instantaneous command of minute anatomical knowledge, a work of this kind keeps the details of the dissecting-room perpetually fresh in the memory.—*The Western Journal of Medicine and Surgery*.

MILLER (HENRY), M. D.,

Professor of Obstetrics and Diseases of Women and Children in the University of Louisville.

PRINCIPLES AND PRACTICE OF OBSTETRICS, &c.; including the Treatment of Chronic Inflammation of the Cervix and Body of the Uterus considered as a frequent cause of Abortion. With about one hundred illustrations on wood. In one very handsome octavo volume, of over 600 pages. (*Lately Published*.) \$3 75.

We congratulate the author that the task is done. We congratulate him that he has given to the medical public a work which will secure for him a high and permanent position among the standard authorities on the principles and practice of obstetrics. Congratulations are not less due to the medical profession of this country, on the acquisition of a treatise embodying the results of the studies, reflections, and experience of Prof. Miller. Few men, if any, in this country, are more competent than he to write on this department of medicine. Engaged for thirty-five years in an extended practice of obstetrics, for many years a teacher of this branch of instruction in one of the largest of our institutions, a diligent student as well as a careful observer, an original and independent thinker, wedded to no hobbies, ever ready to consider without prejudice new views, and to adopt innovations if they are really improvements, and withal a clear, agreeable writer, a practical treatise from his pen could not fail to possess great value.—*Buffalo Med Journal*.

In fact, this volume must take its place among the standard systematic treatises on obstetrics; a posi-

tion to which its merits justly entitle it. The style is such that the descriptions are clear, and each subject is discussed and elucidated with due regard to its practical bearings, which cannot fail to make it acceptable and valuable to both students and practitioners. We cannot, however, close this brief notice without congratulating the author and the profession on the production of such an excellent treatise. The author is a western man of whom we feel proud, and we cannot but think that his book will find many readers and warm admirers wherever obstetrics is taught and studied as a science and an art.—*The Cincinnati Lancet and Observer*.

A most respectable and valuable addition to our home medical literature, and one reflecting credit alike on the author and the institution to which he is attached. The student will find in this work a most useful guide to his studies; the country practitioner, rusty in his reading, can obtain from its pages a fair résumé of the modern literature of the science; and we hope to see this American production generally consulted by the profession.—*Va. Med. Journal*.

MACKENZIE (W.), M. D.,

Surgeon Oculist in Scotland in ordinary to Her Majesty, &c. &c.

A PRACTICAL TREATISE ON DISEASES AND INJURIES OF THE

EYE. To which is prefixed an Anatomical Introduction explanatory of a Horizontal Section of the Human Eyeball, by THOMAS WHARTON JONES, F. R. S. From the Fourth Revised and Enlarged London Edition. With Notes and Additions by ADDINELL HEWSON, M. D., Surgeon to Wills Hospital, &c. &c. In one very large and handsome octavo volume, leather, raised bands, with plates and numerous wood-cuts. \$5 25.

The treatise of Dr. Mackenzie indisputably holds the first place, and forms, in respect of learning and research, an Encyclopedia unequalled in extent by any other work of the kind, either English or foreign.—*Dixon on Diseases of the Eye*.

Few modern books on any department of medicine or surgery have met with such extended circulation, or have procured for their authors a like amount of European celebrity. The immense research which it displayed, the thorough acquaintance with the subject, practically as well as theoretically, and the

able manner in which the author's stores of learning and experience were rendered available for general use, at once procured for the first edition, as well on the continent as in this country, that high position as a standard work which each successive edition has more firmly established. We consider it the duty of every one who has the love of his profession and the welfare of his patient at heart, to make himself familiar with this the most complete work in the English language upon the diseases of the eye.—*Med. Times and Gazette*.

MAYNE'S DISPENSATORY AND THERAPEUTICAL REMEMBRANCER. With every Practical Formula contained in the three British Pharmacopœias Edited, with the addition of the Formulæ of the U. S. Pharmacopœia, by R. E. GRIFFITH, M. D. 112mo. vol. ex. cl. 300 pp. 75 c.

MALGAIGNE'S OPERATIVE SURGERY, based on Normal and Pathological Anatomy. Translated from the French by FREDERICK BRITTON, A. B., M. D. With numerous illustrations on wood. In one handsome octavo volume, extra cloth, of nearly six hundred pages. \$2 25.

MILLER (JAMES), F. R. S. E.,
Professor of Surgery in the University of Edinburgh, &c.

PRINCIPLES OF SURGERY. Fourth American, from the third and revised Edinburgh edition. In one large and very beautiful volume, leather, of 700 pages, with two hundred and forty illustrations on wood \$3 75.

The work of Mr. Miller is too well and too favorably known among us, as one of our best text-books, to render any further notice of it necessary than the announcement of a new edition, the *Fourth* in our country, a proof of its extensive circulation among us. As a concise and reliable exposition of the science of modern surgery, it stands deservedly high—we know not its superior.—*Boston Med. and Surg. Journal*.

The work takes rank with Watson's *Practice of Physic*; it certainly does not fall behind that great work in soundness of principle or depth of reasoning and research. No physician who values his reputation, or seeks the interests of his clients, can acquit himself before his God and the world without making himself familiar with the sound and philosophical views developed in the foregoing hook.—*New Orleans Med. and Surg. Journal*.

BY THE SAME AUTHOR. (*Just Issued.*)

THE PRACTICE OF SURGERY. Fourth American from the last Edinburgh edition. Revised by the American editor. Illustrated by three hundred and sixty-four engravings on wood. In one large octavo volume, leather, of nearly 700 pages. \$3 75.

No encomium of ours could add to the popularity of Miller's *Surgery*. Its reputation in this country is unsurpassed by that of any other work, and, when taken in connection with the author's *Principles of Surgery*, constitutes a whole, without reference to which no conscientious surgeon would be willing to practice his art.—*Southern Med. and Surg. Journal*.

It is seldom that two volumes have ever made so profound an impression in so short a time as the "*Principles*" and the "*Practice*" of Surgery by Mr. Miller—or so richly merited the reputation they have acquired. The author is an eminently sensible, practical, and well-informed man, who knows exactly what he is talking about and exactly how to talk it.—*Kentucky Medical Recorder*.

By the almost unanimous voice of the profession,

his works, both on the principles and practice of surgery have been assigned the highest rank. If we were limited to but one work on surgery, that one should be Miller's, as we regard it as superior to all others.—*St. Louis Med. and Surg. Journal*.

The author has in this and his "*Principles*," presented to the profession one of the most complete and reliable systems of *Surgery extant*. His style of writing is original, impressive, and engaging, energetic, concise, and lucid. Few have the faculty of condensing so much in small space, and at the same time so persistently holding the attention. Whether as a text-book for students or a book of reference for practitioners, it cannot be too strongly recommended.—*Southern Journal of Med. and Physical Sciences*.

MORLAND (W. W.), M. D.,

Fellow of the Massachusetts Medical Society, &c.

DISEASES OF THE URINARY ORGANS; a Compendium of their Diagnosis, Pathology, and Treatment. With illustrations. In one large and handsome octavo volume, of about 600 pages, extra cloth. (*Just Issued.*) \$3 50.

Taken as a whole, we can recommend Dr. Morland's compendium as a very desirable addition to the library of every medical or surgical practitioner.—*Brit. and For. Med.-Chir. Rev.*, April, 1859.

Every medical practitioner whose attention has been to any extent attracted towards the class of diseases to which this treatise relates, must have often and sorely experienced the want of some full, yet concise recent compendium to which he could

refer. This desideratum has been supplied by Dr. Morland, and it has been ably done. He has placed before us a full, judicious, and reliable digest. Each subject is treated with sufficient minuteness, yet in a succinct, narrative style, such as to render the work one of great interest, and one which will prove in the highest degree useful to the general practitioner.—*N. Y. Journ. of Medicine*.

BY THE SAME AUTHOR —(*Now Ready.*)

THE MORBID EFFECTS OF THE RETENTION IN THE BLOOD OF THE ELEMENTS OF THE URINARY SECRETION. Being the Dissertation to which the Fiske Fund Prize was awarded, July 11, 1861. In one small octavo volume, 83 pages, extra cloth. 75 cents.

MONTGOMERY (W. F.), M. D., M. R. I. A., &c.,

Professor of Midwifery in the King and Queen's College of Physicians in Ireland, &c.

AN EXPOSITION OF THE SIGNS AND SYMPTOMS OF PREGNANCY.

With some other Papers on Subjects connected with Midwifery. From the second and enlarged English edition. With two exquisite colored plates, and numerous wood-cuts. In one very handsome octavo volume, extra cloth, of nearly 600 pages. (*Lately Published.*) \$3 75.

A book unusually rich in practical suggestions.—*Am. Journal Med. Sciences*, Jan. 1857.

These several subjects so interesting in themselves, and so important, every one of them, to the most delicate and precious of social relations, controlling often the honor and domestic peace of a family, the legitimacy of offspring, or the life of its parent, are all treated with an elegance of diction, fulness of illustrations, neatness and justice of reasoning, unparalleled in obstetrics, and unsurpassed in medicine. The reader's interest can never flag, so

fresh, and vigorous, and classical is our author's style; and one forgets, in the renewed charm of every page, that it, and every line, and every word has been weighed and reweighed through years of preparation; that this is of all others the book of Obstetric Law, on each of its several topics; on all points connected with pregnancy, to be everywhere received as a manual of special jurisprudence, at once announcing fact, affording argument, establishing precedent, and governing alike the jurymen, advocate, and judge.—*N. A. Med.-Chir. Review*.

MOHR (FRANCIS), PH. D., AND REDWOOD (THEOPHILUS).

PRACTICAL PHARMACY. Comprising the Arrangements, Apparatus, and Manipulations of the Pharmaceutical Shop and Laboratory. Edited, with extensive Additions, by Prof. WILLIAM PROCTER, of the Philadelphia College of Pharmacy. In one handsomely printed octavo volume, extra cloth, of 570 pages, with over 500 engravings on wood. \$2 75.

NEILL (JOHN), M. D.,

Surgeon to the Pennsylvania Hospital, &c.; and

FRANCIS GURNEY SMITH, M. D.,

Professor of Institutes of Medicine in the Pennsylvania Medical College.

AN ANALYTICAL COMPENDIUM OF THE VARIOUS BRANCHES OF MEDICAL SCIENCE; for the Use and Examination of Students. A new edition, revised and improved. In one very large and handsomely printed royal 12mo. volume, of about one thousand pages, with 374 wood-cuts. Strongly bound in leather, with raised bands. \$3 00.

The very flattering reception which has been accorded to this work, and the high estimate placed upon it by the profession, as evinced by the constant and increasing demand which has rapidly exhausted two large editions, have stimulated the authors to render the volume in its present revision more worthy of the success which has attended it. It has accordingly been thoroughly examined, and such errors as had on former occasions escaped observation have been corrected, and whatever additions were necessary to maintain it on a level with the advance of science have been introduced. The extended series of illustrations has been still further increased and much improved, while, by a slight enlargement of the page, these various additions have been incorporated without increasing the bulk of the volume.

The work is, therefore, again presented as eminently worthy of the favor with which it has hitherto been received. As a book for daily reference by the student requiring a guide to his more elaborate text-books, as a manual for preceptors desiring to stimulate their students by frequent and accurate examination, or as a source from which the practitioners of older date may easily and cheaply acquire a knowledge of the changes and improvement in professional science, its reputation is permanently established.

The best work of the kind with which we are acquainted.—*Med. Examiner.*

Having made free use of this volume in our examinations of pupils, we can speak from experience in recommending it as an admirable compend for students, and as especially useful to preceptors who examine their pupils. It will save the teacher much labor by enabling him readily to recall all of the points upon which his pupils should be examined. A work of this sort should be in the hands of every one who takes pupils into his office with a view of examining them; and this is unquestionably the best of its class.—*Transylvania Med. Journal.*

In the rapid course of lectures, where work for

the students is heavy, and review necessary for an examination, a compend is not only valuable, but it is almost a *sine qua non*. The one before us is, in most of the divisions, the most unexceptionable of all books of the kind that we know of. The newest and soundest doctrines and the latest improvements and discoveries are explicitly, though concisely, laid before the student. There is a class to whom we very sincerely commend this cheap book as worth its weight in silver—that class is the graduates in medicine of more than ten years' standing, who have not studied medicine since. They will perhaps find out from it that the science is not exactly now what it was when they left it off.—*The Stethoscope.*

NELIGAN (J. MOORE), M. D., M. R. I. A., &c.

ATLAS OF CUTANEOUS DISEASES. In one beautiful quarto volume, extra cloth, with splendid colored plates, presenting nearly one hundred elaborate representations of disease. \$4 50.

This beautiful volume is intended as a complete and accurate representation of all the varieties of Diseases of the Skin. While it can be consulted in conjunction with any work on Practice, it has especial reference to the author's "Treatise on Diseases of the Skin," so favorably received by the profession some years since. The publishers feel justified in saying that few more beautifully executed plates have ever been presented to the profession of this country.

Neligan's Atlas of Cutaneous Diseases supplies a long existing desideratum much felt by the largest class of our profession. It presents, in quarto size, 16 plates, each containing from 3 to 6 figures, and forming in all a total of 90 distinct representations of the different species of skin affections, grouped together in genera or families. The illustrations have been taken from nature, and have been copied with such fidelity that they present a striking picture of life; in which the reduced scale aptly serves to

give, at a *coup d'œil*, the remarkable peculiarities of each individual variety. And while thus the disease is rendered more definable, there is yet no loss of proportion incurred by the necessary concentration. Each figure is highly colored, and so truthful has the artist been that the most fastidious observer could not justly take exception to the correctness of the execution of the pictures under his scrutiny.—*Montreal Med. Chronicle.*

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON DISEASES OF THE SKIN. Third American edition. In one neat royal 12mo. volume, extra cloth, of 334 pages. \$1 00.

 The two volumes will be sent by mail on receipt of *Five Dollars*.

OWEN ON THE DIFFERENT FORMS OF THE SKELETON, AND OF THE TEETH.

One vol. royal 12mo., extra cloth with numerous illustrations. \$1 25

PIRRIE (WILLIAM), F. R. S. E.,

Professor of Surgery in the University of Aberdeen.

THE PRINCIPLES AND PRACTICE OF SURGERY. Edited by JOHN NEILL, M. D., Professor of Surgery in the Penna. Medical College, Surgeon to the Pennsylvania Hospital, &c. In one very handsome octavo volume, leather, of 780 pages, with 316 illustrations. \$3 75.

We know of no other surgical work of a reasonable size, wherein there is so much theory and practice, or where subjects are more soundly or clearly taught.—*The Stethoscope.*

Prof. Pirrie, in the work before us, has elaborately

discussed the principles of surgery, and a safe and effectual practice predicated upon them. Perhaps no work upon this subject heretofore issued is so full upon the science of the art of surgery.—*Nashville Journal of Medicine and Surgery.*

PARRISH (EDWARD),

Lecturer on Practical Pharmacy and Materia Medica in the Pennsylvania Academy of Medicine, &c.

AN INTRODUCTION TO PRACTICAL PHARMACY. Designed as a Text-Book for the Student, and as a Guide for the Physician and Pharmaceutist. With many Formulæ and Prescriptions. Second edition, greatly enlarged and improved. In one handsome octavo volume of 720 pages, with several hundred Illustrations, extra cloth. \$3 50. (*Just Issued.*)

During the short time in which this work has been before the profession, it has been received with very great favor, and in assuming the position of a standard authority, it has filled a vacancy which had been severely felt. Stimulated by this encouragement, the author, in availing himself of the opportunity of revision, has spared no pains to render it more worthy of the confidence bestowed upon it, and his assiduous labors have made it rather a new book than a new edition, many portions having been rewritten, and much new and important matter added. These alterations and improvements have been rendered necessary by the rapid progress made by pharmaceutical science during the last few years, and by the additional experience obtained in the practical use of the volume as a text-book and work of reference. To accommodate these improvements, the size of the page has been materially enlarged, and the number of pages considerably increased, presenting in all nearly *one-half more* matter than the last edition. The work is therefore now presented as a complete exponent of the subject in its most advanced condition. From the most ordinary matters in the dispensing office, to the most complicated details of the vegetable alkaloids, it is hoped that everything requisite to the practising physician, and to the apothecary, will be found fully and clearly set forth, and that the new matter alone will be worth more than the very moderate cost of the work to those who have been consulting the previous edition.

That Edward Parrish, in writing a book upon practical Pharmacy some few years ago—one eminently original and unique—did the medical and pharmaceutical professions a great and valuable service, no one, we think, who has had access to its pages will deny; doubly welcome, then, is this new edition, containing the added results of his recent and rich experience as an observer, teacher, and practical operator in the pharmaceutical laboratory. The excellent plan of the first is more thoroughly, and in detail, carried out in this edition.—*Peninsular Med. Journal*, Jan. 1860.

Of course, all apothecaries who have not already a copy of the first edition will procure one of this; it is, therefore, to physicians residing in the country and in small towns, who cannot avail themselves of the skill of an educated pharmacist, that we would especially commend this work. In it they

will find all that they desire to know, and should know, but very little of which they do really know in reference to this important collateral branch of their profession; for it is a well established fact, that, in the education of physicians, while the science of medicine is generally well taught, very little attention is paid to the art of preparing them for use, and we know not how this defect can be so well remedied as by procuring and consulting Dr. Parrish's excellent work.—*St. Louis Med. Journal*, Jan. 1860.

We know of no work on the subject which would be more indispensable to the physician or student desiring information on the subject of which it treats. With Griffith's "Medical Formulary" and this, the practising physician would be supplied with nearly or quite all the most useful information on the subject.—*Charleston Med. Jour. and Review*, Jan. 1860

PEASLEE (E. R.), M. D.,

Professor of Physiology and General Pathology in the New York Medical College.

HUMAN HISTOLOGY, in its relations to Anatomy, Physiology, and Pathology; for the use of Medical Students. With four hundred and thirty-four illustrations. In one handsome octavo volume, of over 600 pages. (*Latently Published.*) \$3 75.

It embraces a library upon the topics discussed within itself, and is just what the teacher and learner need. Another advantage, by no means to be overlooked, everything of real value in the wide range which it embraces, is with great skill compressed into an octavo volume of but little more than six hundred pages. We have not only the whole subject of Histology, interesting in itself, ably and fully discussed, but what is of infinitely greater interest to the student, because of greater practical value, are its relations to Anatomy, Physiology, and Pathology, which are here fully and satisfactorily set forth.—*Nashville Journ. of Med. and Surgery*.

We would recommend it to the medical student and practitioner, as containing a summary of all that is known of the important subjects which it treats; of all that is contained in the great works of Simon and Lehmann, and the organic chemists in general. Master this one volume, we would say to the medical student and practitioner—master this book and you know all that is known of the great fundamental principles of medicine, and we have no hesitation in saying that it is an honor to the American medical profession that one of its members should have produced it.—*St. Louis Med. and Surg. Journal*.

PEREIRA (JONATHAN), M. D., F. R. S., AND L. S.

THE ELEMENTS OF MATERIA MEDICA AND THERAPEUTICS.

Third American edition, enlarged and improved by the author; including Notices of most of the Medicinal Substances in use in the civilized world, and forming an Encyclopædia of Materia Medica. Edited, with Additions, by JOSEPH CARSON, M. D., Professor of Materia Medica and Pharmacy in the University of Pennsylvania. In two very large octavo volumes of 2100 pages, on small type, with about 500 illustrations on stone and wood, strongly bound in leather, with raised bands. \$9 00.

*** Vol. II. will no longer be sold separate.

PARKER (LANGSTON),

Surgeon to the Queen's Hospital, Birmingham.

THE MODERN TREATMENT OF SYPHILITIC DISEASES, BOTH PRIMARY AND SECONDARY; comprising the Treatment of Constitutional and Confirmed Syphilis, by a safe and successful method. With numerous Cases, Formulæ, and Clinical Observations. From the Third and entirely rewritten London edition. In one neat octavo volume, extra cloth, of 316 pages. \$1 75.

ROYLE'S MATERIA MEDICA AND THERAPEUTICS; including the Preparations of the Pharmacopœias of London, Edinburgh, Dublin, and of the United States.

With many new medicines. Edited by JOSEPH CARSON, M. D. With ninety-eight illustrations. In one large octavo volume, extra cloth, of about 700 pages. \$3 00.

RAMSBOTHAM (FRANCIS H.), M.D.

THE PRINCIPLES AND PRACTICE OF OBSTETRIC MEDICINE AND SURGERY, in reference to the Process of Parturition. A new and enlarged edition, thoroughly revised by the Author. With Additions by W. V. KEATING, M. D., Professor of Obstetrics, &c., in the Jefferson Medical College, Philadelphia. In one large and handsome imperial octavo volume, of 650 pages, strongly bound in leather, with raised bands; with sixty-four beautiful Plates, and numerous Wood-cuts in the text, containing in all nearly 200 large and beautiful figures. \$5 00.

From Prof. Hodge, of the University of Pa.

To the American public, it is most valuable, from its intrinsic undoubted excellence, and as being the best authorized exponent of British Midwifery. Its circulation will, I trust, be extensive throughout our country.

It is unnecessary to say anything in regard to the utility of this work. It is already appreciated in our country for the value of the matter, the clearness of its style, and the fulness of its illustrations. To the physician's library it is indispensable, while to the student as a text-book, from which to extract the material for laying the foundation of an education on obstetrical science, it has no superior.—*Ohio Med and Surg. Journal*.

The publishers have secured its success by the

truly elegant style in which they have brought it out, excelling themselves in its production, especially in its plates. It is dedicated to Prof. Meigs, and has the emphatic endorsement of Prof. Hodge, as the best exponent of British Midwifery. We know of no text-book which deserves in all respects to be more highly recommended to students, and we could wish to see it in the hands of every practitioner, for they will find it invaluable for reference.—*Med. Gazette*.

RICORD (P.), M.D.

A TREATISE ON THE VENEREAL DISEASE. By JOHN HUNTER, F.R.S.

With copious Additions, by PH. RICORD, M.D. Translated and Edited, with Notes, by FREEMAN J. BUMSTEAD, M.D., Lecturer on Venereal at the College of Physicians and Surgeons, New York. Second edition, revised, containing a *résumé* of RICORD'S RECENT LECTURES ON CHANCERE. In one handsome octavo volume, extra cloth, of 550 pages, with eight plates. \$3 25. (*Just Issued*.)

In revising this work, the editor has endeavored to introduce whatever matter of interest the recent investigations of syphilographers have added to our knowledge of the subject. The principal source from which this has been derived is the volume of "Lectures on Chancere," published a few months since by M. Ricord, which affords a large amount of new and instructive material on many controverted points. In the previous edition, M. Ricord's additions amounted to nearly one-third of the whole, and with the matter now introduced, the work may be considered to present his views and experience more thoroughly and completely than any other.

Every one will recognize the attractiveness and value which this work derives from thus presenting the opinions of these two masters side by side. But, it must be admitted, what has made the fortune of the book, is the fact that it contains the "most complete embodiment of the veritable doctrines of the Hôpital du Midi," which has ever been made public. The doctrinal ideas of M. Ricord, ideas which, if not universally adopted, are incontestably dominant, have heretofore only been interpreted by more or less skilful

secretaries, sometimes accredited and sometimes not.

In the notes to Hunter, the master substitutes himself for his interpreters, and gives his original thoughts to the world in a lucid and perfectly intelligible manner. In conclusion we can say that this is incontestably the best treatise on syphilis with which we are acquainted, and, as we do not often employ the phrase, we may be excused for expressing the hope that it may find a place in the library of every physician.—*Virginia Med. and Surg. Journal*.

BY THE SAME AUTHOR.

RICORD'S LETTERS ON SYPHILIS. Translated by W. P. LATTIMORE, M.D.

In one neat octavo volume, of 270 pages, extra cloth. \$2 00.

ROKITANSKY (CARL), M.D.,

Curator of the Imperial Pathological Museum, and Professor at the University of Vienna, &c.

A MANUAL OF PATHOLOGICAL

bound in two extra cloth, of about 1200 pages. KING, C. H. MOORE, and G. E. DAY. \$5 50.

The profession is too well acquainted with the reputation of Rokitansky's work to need our assurance that this is one of the most profound, thorough, and valuable books ever issued from the medical press. It is *sui generis*, and has no standard of comparison. It is only necessary to announce that it is issued in a form as cheap as is compatible with its size and preservation, and its sale follows as a matter of course. No library can be called complete without it.—*Buffalo Med. Journal*.

An attempt to give our readers any adequate idea of the vast amount of instruction accumulated in these volumes, would be feeble and hopeless. The effort of the distinguished author to concentrate in a small space his great fund of knowledge, has

ANATOMY. Four volumes, octavo,

Translated by W. E. SWAINE, EDWARD SIEVE-

so charged his text with valuable truths, that any attempt of a reviewer to epitomize is at once paralyzed, and must end in a failure.—*Western Lancet*.

As this is the highest source of knowledge upon the important subject of which it treats, no real student can afford to be without it. The American publishers have entitled themselves to the thanks of the profession of their country, for this timely and beautiful edition.—*Nashville Journal of Medicine*.

As a book of reference, therefore, this work must prove of inestimable value, and we cannot too highly recommend it to the profession.—*Charleston Med. Journal and Review*.

This book is a necessity to every practitioner.—*Am. Med. Monthly*.

RIGBY (EDWARD), M.D.,

Senior Physician to the General Lying-in Hospital, &c.

A SYSTEM OF MIDWIFERY. With Notes and Additional Illustrations.

Second American Edition. One volume octavo, extra cloth, 422 pages. \$2 50.

BY THE SAME AUTHOR. (*Lately Published*.)

ON THE CONSTITUTIONAL TREATMENT OF FEMALE DISEASES.

In one neat royal 12mo. volume, extra cloth, of about 250 pages. \$1 00.

STILLE (ALFRED), M. D.

THERAPEUTICS AND MATERIA MEDICA; a Systematic Treatise on the

Action and Uses of Medicinal Agents, including their Description and History. In two large and handsome octavo volumes, of 1789 pages. (Just Issued.) \$8 00.

This work is designed especially for the student and practitioner of medicine, and treats the various articles of the *Materia Medica* from the point of view of the bed-side, and not of the shop or of the lecture-room. While thus endeavoring to give all practical information likely to be useful with respect to the employment of special remedies in special affections, and the results to be anticipated from their administration, a copious Index of Diseases and their Remedies renders the work eminently fitted for reference by showing at a glance the different means which have been employed, and enabling the practitioner to extend his resources in difficult cases with all that the experience of the profession has suggested.

Rarely, indeed, have we had submitted to us a work on medicine so ponderous in its dimensions as that now before us, and yet so fascinating in its contents. It is, therefore, with a peculiar gratification that we recognize in Dr. Stille the possession of many of those more distinguished qualifications which entitle him to approbation, and which justify him in coming before his medical brethren as an instructor. A comprehensive knowledge, tested by a sound and penetrating judgment, joined to a love of progress—which a discriminating spirit of inquiry has tempered so as to accept nothing new because it is new, and abandon nothing old because it is old, but which estimates either according to its relations to a just logic and experience—manifests itself everywhere, and gives to the guidance of the author all the assurance of safety which the difficulties of his subject can allow. In conclusion, we earnestly advise our readers to ascertain for themselves, by a study of Dr. Stille's volumes, the great value and interest of the stores of knowledge they present. We have pleasure in referring rather to the ample treasury of undoubted truths, the real and assured conquest of medicine, accumulated by Dr. Stille in his pages; and commend the sum of his labors to the attention of our readers, as alike honorable to our science, and creditable to the zeal, the candor, and the judgment of him who has garnered the whole so carefully.—*Edinburgh Med. Journal.*

Our expectations of the value of this work were based on the well-known reputation and character of the author as a man of scholarly attainments, an elegant writer, a candid inquirer after truth, and a philosophical thinker; we knew that the task would be conscientiously performed, and that few, if any, among the distinguished medical teachers in this country are better qualified than he to prepare a systematic treatise on therapeutics in accordance with the present requirements of medical science. Our preliminary examination of the work has satis-

fied us that we were not mistaken in our anticipations.—*New Orleans Medical News*, March, 1860.

The most recent authority is the one last mentioned, Stille. His great work on "*Materia Medica and Therapeutics*," published last year, in two octavo volumes, of some sixteen hundred pages, while it embodies the results of the labor of others up to the time of publication, is enriched with a great amount of original observation and research. We would draw attention, by the way, to the very convenient mode in which the *Index* is arranged in this work. There is first an "*Index of Remedies*;" next an "*Index of Diseases and their Remedies*." Such an arrangement of the Indices, in our opinion, greatly enhances the practical value of books of this kind. In tedious, obstinate cases of disease, where we have to try one remedy after another until our stock is pretty nearly exhausted, and we are almost driven to our wit's end, such an index as the second of the two just mentioned, is precisely what we want.—*London Med. Times and Gazette*, April, 1861.

We think this work will do much to obviate the reluctance to a thorough investigation of this branch of scientific study, for in the wide range of medical literature treasured in the English tongue, we shall hardly find a work written in a style more clear and simple, conveying forcibly the facts taught, and yet free from turgidity and redundancy. There is a fascination in its pages that will insure to it a wide popularity and attentive perusal, and a degree of usefulness not often attained through the influence of a single work. The author has much enhanced the practical utility of his book by passing briefly over the physical, botanical, and commercial history of medicines, and directing attention chiefly to their physiological action, and their application for the amelioration or cure of disease. He ignores hypothesis and theory which are so alluring to many medical writers, and so liable to lead them astray, and confines himself to such facts as have been tried in the crucible of experience.—*Chicago Medical Journal.*

SMITH (HENRY H.), M. D. AND HORNER (WILLIAM E.), M. D.

AN ANATOMICAL ATLAS, illustrative of the Structure of the Human Body.

In one volume, large imperial octavo, extra cloth, with about six hundred and fifty beautiful figures. \$3 00.

These figures are well selected, and present a complete and accurate representation of that wonderful fabric, the human body. The plan of this Atlas, which renders it so peculiarly convenient for the student, and its superb artistic execution, have been already pointed out. We must congratulate the student upon the completion of this Atlas as it is the most convenient work of the kind that has yet appeared; and we must add, the very beautiful manner in which it is "got up" is so creditable to the country as to be flattering to our national pride.—*American Medical Journal.*

SHARPEY (WILLIAM), M. D., JONES QUAIN, M. D., AND RICHARD QUAIN, F. R. S., &c.

HUMAN ANATOMY. Revised, with Notes and Additions, by JOSEPH LEIDY,

M. D., Professor of Anatomy in the University of Pennsylvania. Complete in two large octavo volumes, leather, of about thirteen hundred pages. Beautifully illustrated with over five hundred engravings on wood. \$6 00.

SIMPSON (J. Y.), M. D.,

Professor of Midwifery, &c., in the University of Edinburgh, &c.

CLINICAL LECTURES ON THE DISEASES OF FEMALES. With numerous illustrations.

This valuable series of practical Lectures is now appearing in the "*MEDICAL NEWS AND LIBRARY*" for 1860, 1861, and 1862, and can thus be had without cost by subscribers to the "*AMERICAN JOURNAL OF THE MEDICAL SCIENCES*." See p. 2.

SOLLY ON THE HUMAN BRAIN; its Structure, Physiology, and Diseases. From the Second and much enlarged London edition. In one octavo volume, extra cloth, of 500 pages, with 120 woodcuts. \$2 00.

SKEY'S OPERATIVE SURGERY. In one very

handsome octavo volume, extra cloth, of over 650 pages, with about one hundred woodcuts. \$3 25.

SIMON'S GENERAL PATHOLOGY, as conducive to the Establishment of Rational Principles for the prevention and Cure of Disease. In one octavo volume, extra cloth, of 212 pages. \$1 25.

SARGENT (F. W.), M. D.

ON BANDAGING AND OTHER OPERATIONS OF MINOR SURGERY.

New edition, with an additional chapter on Military Surgery. One handsome royal 12mo. vol., of nearly 400 pages, with 184 wood cuts. Leather, \$1 50. (*Now Ready.*)

The value of this work as a handy and convenient manual for surgeons engaged in active duty in the field and hospital, has induced the publishers to render it more complete for those purposes by the addition of a chapter on gun-shot wounds and other matters peculiar to military surgery. In its present form, therefore, with no increase in price, it will be found a very cheap and convenient vade-mecum for consultation and reference in the daily exigencies of military as well as civil practice.

We have read Bourgerie's Minor Surgery with pleasure and profit, but in many respects the volume now before us immeasurably transcends it. We consider that no better book could be placed in the hands of an hospital dresser, or the young surgeon, whose education in this respect has not been perfected. We most cordially commend this volume as one which the medical student should most closely study, to perfect himself in these minor surgical operations in which neatness and dexterity are so much required, and on which a great portion of his reputation as a future surgeon must evidently rest. And to the surgeon in practice it must prove itself a valuable volume, as instructive on many points which he may have forgotten.—*British American Journal*, May, 1862.

The instruction given upon the subject of *Bandaging*, is alone of great value, and while the author modestly proposes to instruct the students of medicine, and the younger physicians, we will say that experienced physicians will obtain many exceedingly valuable suggestions by its perusal. Without attempting to particularize further, we will conclude our brief notice by saying, that it will be found one of the most satisfactory manuals for reference in the field, or hospital yet published; thoroughly adapted to the wants of Military surgeons, and at the same time equally useful for ready and convenient reference by surgeons everywhere.—*Buffalo Med. and Surg. Journal*, June, 1862.

SMITH (W. TYLER), M. D.,

Physician Accoucheur to St. Mary's Hospital, &c.

ON PARTURITION, AND THE PRINCIPLES AND PRACTICE OF OBSTETRICS. In one royal 12mo. volume, extra cloth, of 400 pages. \$1 25.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE PATHOLOGY AND TREATMENT OF LEUCORRHEA. With numerous illustrations. In one very handsome octavo volume, extra cloth, of about 250 pages. \$1 50.

TANNER (T. H.), M. D.,

Physician to the Hospital for Women, &c.

A MANUAL OF CLINICAL MEDICINE AND PHYSICAL DIAGNOSIS.

To which is added The Code of Ethics of the American Medical Association. Second American Edition. In one neat volume, small 12mo., extra cloth, 87½ cents.

TAYLOR (ALFRED S.), M. D., F. R. S.,

Lecturer on Medical Jurisprudence and Chemistry in Guy's Hospital.

MEDICAL JURISPRUDENCE. Fifth American, from the seventh improved and enlarged London edition. With Notes and References to American Decisions, by EDWARD HARTSHORNE, M. D. In one large 8vo. volume, leather, of over 700 pages. (*Now Ready.*) \$3 25.

This standard work having had the advantage of two revisions at the hands of the author since the appearance of the last American edition, will be found thoroughly revised and brought up completely to the present state of the science. As a work of authority, it must therefore maintain its position, both as a text-book for the student, and a compendious treatise to which the practitioner can at all times refer in cases of doubt or difficulty.

No work upon the subject can be put into the hands of students either of law or medicine which will engage them more closely or profitably; and none could be offered to the busy practitioner of either calling, for the purpose of casual or hasty reference, that would be more likely to afford the aid desired. We therefore recommend it as the best and safest manual for daily use.—*American Journal of Medical Sciences*.

It is not excess of praise to say that the volume before us is the very best treatise extant on Medical Jurisprudence. In saying this, we do not wish to be understood as detracting from the merits of the excellent works of Beck, Ryan, Traill, Guy, and others; but in interest and value we think it must be conceded that Taylor is superior to anything that has preceded it.—*N. W. Medical and Surg. Journal*

It is at once comprehensive and eminently practical, and by universal consent stands at the head of

American and British legal medicine. It should be in the possession of every physician, as the subject is one of great and increasing importance to the public as well as to the profession.—*St. Louis Med. and Surg. Journal*.

This work of Dr. Taylor's is generally acknowledged to be one of the ablest extant on the subject of medical jurisprudence. It is certainly one of the most attractive books that we have met with; supplying so much both to interest and instruct, that we do not hesitate to affirm that after having once commenced its perusal, few could be prevailed upon to desist before completing it. In the last London edition, all the newly observed and accurately recorded facts have been inserted, including much that is recent of Chemical, Microscopical, and Pathological research, besides papers on numerous subjects never before published.—*Charleston Med. Journal and Review*.

BY THE SAME AUTHOR.

ON POISONS, IN RELATION TO MEDICAL JURISPRUDENCE AND MEDICINE. Second American, from a second and revised London edition. In one large octavo volume, of 755 pages, leather. \$3 50.

Mr. Taylor's position as the leading medical jurist of England, has conferred on him extraordinary advantages in acquiring experience on these subjects, nearly all cases of moment being referred to him for examination, as an expert whose testimony is generally accepted as final. The results of his labors, therefore, as gathered together in this volume, carefully weighed and sifted, and presented in the clear and intelligible style for which he is noted, may be received as an acknowledged authority, and as a guide to be followed with implicit confidence.

TODD (ROBERT BENTLEY), M. D., F. R. S.,
Professor of Physiology in King's College, London; and

WILLIAM BOWMAN, F. R. S.,
Demonstrator of Anatomy in King's College, London.

THE PHYSIOLOGICAL ANATOMY AND PHYSIOLOGY OF MAN. With about three hundred large and beautiful illustrations on wood. Complete in one large octavo volume, of 950 pages, leather. Price \$4 50.

☞ Gentlemen who have received portions of this work, as published in the "MEDICAL NEWS AND LIBRARY," can now complete their copies, if immediate application be made. It will be furnished as follows, free by mail, in paper covers, with cloth backs.

PARTS I., II., III. (pp. 25 to 552), \$2 50.

PART IV. (pp. 553 to end, with Title, Preface, Contents, &c.), \$2 00.

Or, PART IV., SECTION II. (pp. 725 to end, with Title, Preface, Contents, &c.), \$1 25.

A magnificent contribution to British medicine, and the American physician who shall fail to peruse it, will have failed to read one of the most instructive books of the nineteenth century.—*N. O. Med and Surg. Journal*.

It is more concise than Carpenter's Principles, and more modern than the accessible edition of Muller's Elements; its details are brief, but sufficient; its descriptions vivid; its illustrations exact and copious; and its language terse and perspicuous.—*Charleston Med. Journal*.

We know of no work on the subject of physiology

so well adapted to the wants of the medical student. Its completion has been thus long delayed, that the authors might secure accuracy by personal observation.—*St. Louis Med. and Surg. Journal*.

Our notice, though it conveys but a very feeble and imperfect idea of the magnitude and importance of the work now under consideration, already transcends our limits; and, with the indulgence of our readers, and the hope that they will peruse the book for themselves, as we feel we can with confidence recommend it, we leave it in their hands.—*The Northwestern Med. and Surg. Journal*.

TODD (R. B.) M. D., F. R. S., &c.

CLINICAL LECTURES ON CERTAIN DISEASES OF THE URINARY ORGANS AND ON DROPSIES. In one octavo volume, 284 pages. \$1 50.

BY THE SAME AUTHOR. (*Now Ready.*)

CLINICAL LECTURES ON CERTAIN ACUTE DISEASES. In one neat octavo volume, of 320 pages, extra cloth. \$1 75.

TOYNBEE (JOSEPH), F. R. S.,

Aural Surgeon to, and Lecturer on Surgery at, St. Mary's Hospital.

A PRACTICAL TREATISE ON DISEASES OF THE EAR; their Diagnosis, Pathology, and Treatment. Illustrated with one hundred engravings on wood. In one very handsome octavo volume, extra cloth, \$3 00. (*Just Issued.*)

The work, as was stated at the outset of our notice, is a model of its kind, and every page and paragraph of it are worthy of the most thorough study. Considered all in all—as an original work, well written, philosophically elaborated, and happily illustrated with cases and drawings—it is by far the ablest monograph that has ever appeared on the anatomy and diseases of the ear, and one of the most valuable contributions to the art and science of surgery in the nineteenth century.—*N. Amer. Medico-Chirurg. Review*, Sept. 1860.

To recommend such a work, even after the mere hint we have given of its original excellence and value, would be a work of supererogation. We are speaking within the limits of modest acknowledg-

ment, and with a sincere and unbiassed judgment, when we affirm that as a treatise on Aural Surgery, it is without a rival in our language or any other.—*Charleston Med. Journ. and Review*, Sept. 1860.

The work of Mr. Toynbee is undoubtedly, upon the whole, the most valuable production of the kind in any language. The author has long been known by his numerous monographs upon subjects connected with diseases of the ear, and is now regarded as the highest authority on most points in his department of science. Mr. Toynbee's work, as we have already said, is undoubtedly the most reliable guide for the study of the diseases of the ear in any language, and should be in the library of every physician.—*Chicago Med. Journal*, July, 1860.

WILLIAMS (C. J. B.), M. D., F. R. S.,

Professor of Clinical Medicine in University College, London, &c.

PRINCIPLES OF MEDICINE. An Elementary View of the Causes, Nature, Treatment, Diagnosis, and Prognosis of Disease; with brief remarks on Hygienics, or the preservation of health. A new American, from the third and revised London edition. In one octavo volume, leather, of about 500 pages. \$2 50. (*Just Issued.*)

We find that the deeply-interesting matter and style of this book have so far fascinated us, that we have unconsciously hung upon its pages, not too long, indeed, for our own profit, but longer than reviewers can be permitted to indulge. We leave the further analysis to the student and practitioner. Our judgment of the work has already been sufficiently

expressed. It is a judgment of almost unqualified praise.—*London Lancet*.

A text-book to which no other in our language is comparable.—*Charleston Medical Journal*.

No work has ever achieved or maintained a more deserved reputation.—*Va. Med. and Surg. Journal*.

WHAT TO OBSERVE

AT THE BEDSIDE AND AFTER DEATH, IN MEDICAL CASES.

Published under the authority of the London Society for Medical Observation. A new American, from the second and revised London edition. In one very handsome volume, royal 12mo., extra cloth. \$1 00.

To the observer who prefers accuracy to blunders and precision to carelessness, this little book is invaluable.—*N. H. Journal of Medicine*.

One of the finest aids to a young practitioner we have ever seen.—*Pennsular Journal of Medicine*.

New and much enlarged edition—(Just Issued.)

WATSON (THOMAS), M. D., &c.,

Late Physician to the Middlesex Hospital, &c.

LECTURES ON THE PRINCIPLES AND PRACTICE OF PHYSIC.

Delivered at King's College, London. A new American, from the last revised and enlarged English edition, with Additions, by D. FRANCIS CONDIE, M. D., author of "A Practical Treatise on the Diseases of Children," &c. With one hundred and eighty-five illustrations on wood. In one very large and handsome volume, imperial octavo, of over 1200 closely printed pages in small type; the whole strongly bound in leather, with raised bands. Price \$4 25.

That the high reputation of this work might be fully maintained, the author has subjected it to a thorough revision; every portion has been examined with the aid of the most recent researches in pathology, and the results of modern investigations in both theoretical and practical subjects have been carefully weighed and embodied throughout its pages. The watchful scrutiny of the editor has likewise introduced whatever possesses immediate importance to the American physician in relation to diseases incident to our climate which are little known in England, as well as those points in which experience here has led to different modes of practice; and he has also added largely to the series of illustrations, believing that in this manner valuable assistance may be conveyed to the student in elucidating the text. The work will, therefore, be found thoroughly on a level with the most advanced state of medical science on both sides of the Atlantic.

The additions which the work has received are shown by the fact that notwithstanding an enlargement in the size of the page, more than two hundred additional pages have been necessary to accommodate the two large volumes of the London edition (which sells at ten dollars), within the compass of a single volume, and in its present form it contains the matter of at least three ordinary octavos. Believing it to be a work which should lie on the table of every physician, and be in the hands of every student, the publishers have put it at a price within the reach of all, making it one of the cheapest books as yet presented to the American profession, while at the same time the beauty of its mechanical execution renders it an exceedingly attractive volume.

The fourth edition now appears, so carefully revised, as to add considerably to the value of a book already acknowledged, wherever the English language is read, to be beyond all comparison the best systematic work on the Principles and Practice of Physic in the whole range of medical literature. Every lecture contains proof of the extreme anxiety of the author to keep pace with the advancing knowledge of the day, and to bring the results of the labors, not only of physicians, but of chemists and histologists, before his readers, wherever they can be turned to useful account. One scarcely knows whether to admire most the pure, simple, forcible English—the vast amount of useful practical information condensed into the Lectures—or the manly, kind-hearted, unassuming character of the lecturer shining through his work.—*London Med. Times*.

Thus these admirable volumes come before the profession in their fourth edition, abounding in those distinguished attributes of moderation, judgment, erudite cultivation, clearness, and eloquence, with which they were from the first invested, but yet richer than before in the results of more prolonged observation, and in the able appreciation of the latest advances in pathology and medicine by one of the most profound medical thinkers of the day.—*London Lancet*.

The lecturer's skill, his wisdom, his learning, are equalled by the ease of his graceful diction, his eloquence, and the far higher qualities of candor, of courtesy, of modesty, and of generous appreciation of merit in others.—*N. A. Med.-Chir. Review*.

Watson's unrivalled, perhaps unapproachable work on Practice—the copious additions made to which (the fourth edition) have given it all the novelty and much of the interest of a new book.—*Charleston Med. Journal*.

Lecturers, practitioners, and students of medicine will equally hail the reappearance of the work of Dr. Watson in the form of a new—a fourth—edition. We merely do justice to our own feelings, and, we are sure, of the whole profession, if we thank him for having, in the trouble and turmoil of a large practice, made leisure to supply the hiatus caused by the exhaustion of the publisher's stock of the third edition, which has been severely felt for the last three years. For Dr. Watson has not merely caused the lectures to be reprinted, but scattered through the whole work we find additions or alterations which prove that the author has in every way sought to bring up his teaching to the level of the most recent acquisitions in science.—*Brit. and For. Medico-Chir. Review*.

WALSHE (W. H.), M. D.,

Professor of the Principles and Practice of Medicine in University College, London, &c.

A PRACTICAL TREATISE ON DISEASES OF THE LUNGS; including the Principles of Physical Diagnosis. A new American, from the third revised and much enlarged London edition. In one vol. octavo, of 468 pages. \$2 25.

The present edition has been carefully revised and much enlarged, and may be said in the main to be rewritten. Descriptions of several diseases, previously omitted, are now introduced; the causes and mode of production of the more important affections, so far as they possess direct practical significance, are succinctly inquired into; an effort has been made to bring the description of anatomical characters to the level of the wants of the practical physician; and the diagnosis and prognosis of each complaint are more completely considered. The sections on TREATMENT and the Appendix (concerning the influence of climate on pulmonary disorders), have, especially, been largely extended.—*Author's Preface*.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DISEASES OF THE HEART AND GREAT VESSELS, including the Principles of Physical Diagnosis. Third American, from the third revised and much enlarged London edition. In one handsome octavo volume of 420 pages, extra cloth. \$2 25. (Just Ready.)

From the Author's Preface.

The present edition has been carefully revised; much new matter has been added, and the entire work in a measure remodelled. Numerous facts and discussions, more or less completely novel, will be found in the description of the principles of physical diagnosis; but the chief additions have been made in the practical portions of the book. Several affections, of which little or no account had been given in the previous editions, are now treated of in detail. Functional disorders of the heart, the frequency of which is almost rivalled by the misery they inflict, have been closely reconsidered; more especially an attempt has been made to render their essential nature clearer, and consequently their treatment more successful, by an analysis of their dynamic elements.

New and much enlarged edition—(Just Issued.)

WILSON (ERASMUS), F. R. S.

A SYSTEM OF HUMAN ANATOMY, General and Special. A new and revised American, from the last and enlarged English Edition. Edited by W. H. GÖBRECHT, M. D., Professor of Anatomy in the Pennsylvania Medical College, &c. Illustrated with three hundred and ninety-seven engravings on wood. In one large and exquisitely printed octavo volume, of over 600 large pages; leather. \$3 25.

The publishers trust that the well earned reputation so long enjoyed by this work will be more than maintained by the present edition. Besides a very thorough revision by the author, it has been most carefully examined by the editor, and the efforts of both have been directed to introducing everything which increased experience in its use has suggested as desirable to render it a complete text-book for those seeking to obtain or to renew an acquaintance with Human Anatomy. The amount of additions which it has thus received may be estimated from the fact that the present edition contains over one-fourth more matter than the last, rendering a smaller type and an enlarged page requisite to keep the volume within a convenient size. The editor has exercised the utmost caution to obtain entire accuracy in the text, and has largely increased the number of illustrations, of which there are about one hundred and fifty more in this edition than in the last, thus bringing distinctly before the eye of the student everything of interest or importance.

It may be recommended to the student as no less distinguished by its accuracy and clearness of description than by its typographical elegance. The wood-cuts are exquisite.—*Brit. and For. Medical Review*.

An elegant edition of one of the most useful and accurate systems of anatomical science which has been issued from the press. The illustrations are really beautiful. In its style the work is extremely concise and intelligible. No one can possibly take up this volume without being struck with the great

beauty of its mechanical execution, and the clearness of the descriptions which it contains is equally evident. Let students, by all means examine the claims of this work on their notice, before they purchase a text-book of the vitally important science which this volume so fully and easily unfolds.—*Lancet*.

We regard it as the best system now extant for students.—*Western Lancet*.

It therefore receives our highest commendation.—*Southern Med. and Surg. Journal*.

BY THE SAME AUTHOR. (Just Issued.)

ON DISEASES OF THE SKIN. Fourth and enlarged American, from the last and improved London edition. In one large octavo volume, of 650 pages, extra cloth, \$2 75.

The writings of Wilson, upon diseases of the skin, are by far the most scientific and practical that have ever been presented to the medical world on this subject. The present edition is a great improvement on all its predecessors. To dwell upon all the great merits and high claims of the work before us, *seriatim*, would indeed be an agreeable service; it would be a mental homage which we could freely offer, but we should thus occupy an undue amount of space in this *Journal*. We will, however, look

at some of the more salient points with which it abounds, and which make it incomparably superior in excellence to all other treatises on the subject of dermatology. No mere speculative views are allowed a place in this volume, which, without a doubt, will, for a very long period, be acknowledged as the chief standard work on dermatology. The principles of an enlightened and rational therapeia are introduced on every appropriate occasion.—*Am. Jour. Med. Science*, Oct. 1857.

ALSO, NOW READY,

A SERIES OF PLATES ILLUSTRATING WILSON ON DISEASES OF THE SKIN; consisting of nineteen beautifully executed plates, of which twelve are exquisitely colored, presenting the Normal Anatomy and Pathology of the Skin, and containing accurate representations of about one hundred varieties of disease, most of them the size of nature. Price in cloth \$4 25.

In beauty of drawing and accuracy and finish of coloring these plates will be found equal to anything of the kind as yet issued in this country.

The plates by which this edition is accompanied leave nothing to be desired, so far as excellence of delineation and perfect accuracy of illustration are concerned.—*Medico-Chirurgical Review*.

Of these plates it is impossible to speak too highly. The representations of the various forms of cutaneous disease are singularly accurate, and the coloring exceeds almost anything we have met with in point of delicacy and finish.—*British and Foreign Medical Review*.

We have already expressed our high appreciation of Mr. Wilson's treatise on Diseases of the Skin. The plates are comprised in a separate volume, which we counsel all those who possess the text to purchase. It is a beautiful specimen of color printing, and the representations of the various forms of skin disease are as faithful as is possible in plates of the size.—*Boston Med. and Surg. Journal*, April 8, 1853.

BY THE SAME AUTHOR.

ON CONSTITUTIONAL AND HEREDITARY SYPHILIS, AND ON SYPHILITIC ERUPTIONS. In one small octavo volume, extra cloth, beautifully printed, with four exquisite colored plates, presenting more than thirty varieties of syphilitic eruptions. \$2 25.

BY THE SAME AUTHOR.

HEALTHY SKIN; A Popular Treatise on the Skin and Hair, their Preservation and Management. Second American, from the fourth London edition. One neat volume, royal 12mo., extra cloth, of about 300 pages, with numerous illustrations. \$1 00; paper cover, 75 cents.

BY THE SAME AUTHOR.

THE DISSECTOR'S MANUAL; or, Practical and Surgical Anatomy. Third American, from the last revised and enlarged English edition. Modified and rearranged, by WILLIAM HUNT, M. D., Demonstrator of Anatomy in the University of Pennsylvania. In one large and handsome royal 12mo. volume, leather, of 582 pages, with 154 illustrations. \$2 00.

WINSLOW (FORBES), M. D., D. C. L., &c.

ON OBSCURE DISEASES OF THE BRAIN AND DISORDERS OF THE MIND; their incipient Symptoms, Pathology, Diagnosis, Treatment, and Prophylaxis. In one handsome octavo volume, of nearly 600 pages. (Just Issued.) \$3 00.

We close this brief and necessarily very imperfect notice of Dr. Winslow's great and classical work, by expressing our conviction that it is long since so important and beautifully written a volume has issued from the British medical press.—*Dublin Med. Press*, July 25, 1860.

We honestly believe this to be the best book of the season.—*Ranking's Abstract*, July, 1860.

It carried us back to our old days of novel reading, it kept us from our dinner, from our business, and from our slumbers; in short, we laid it down only when we had got to the end of the last paragraph, and even then turned back to the re-perusal of several passages which we had marked as requiring further study. We have failed entirely in the above notice to give an adequate acknowledgment of the profit and pleasure with which we have perused the above work. We can only say to our readers, study it

yourselves; and we extend the invitation to unprofessional as well as professional men, believing that it contains matter deeply interesting not to physicians alone, but to all who appreciate the truth that: "The proper study of mankind is man."—*Nashville Medical Record*, July, 1860.

The latter portion of Dr. Winslow's work is exclusively devoted to the consideration of Cerebral Pathology. It completely exhausts the subject, in the same manner as the previous seventeen chapters relating to morbid psychical phenomena left nothing unnoticed in reference to the mental symptoms premonitory of cerebral disease. It is impossible to overrate the benefits likely to result from a general perusal of Dr. Winslow's valuable and deeply interesting work.—*London Lancet*, June 23, 1860.

It contains an immense mass of information.—*Brit. and For. Med.-Chir. Review*, Oct. 1860.

WEST (CHARLES), M. D.,

Accoucheur to and Lecturer on Midwifery at St. Bartholomew's Hospital, Physician to the Hospital for Sick Children, &c.

LECTURES ON THE DISEASES OF WOMEN. Second American, from the second London edition. In one handsome octavo volume, extra cloth, of about 500 pages; price \$2 50. (Now Ready, July, 1861.)

* Gentlemen who received the first portion, as issued in the "Medical News and Library," can now complete their copies by procuring Part II, being page 309 to end, with Index, Title matter, &c., 8vo., cloth, price \$1.

We must now conclude this hastily written sketch with the confident assurance to our readers that the work will well repay perusal. The conscientious, painstaking, practical physician is apparent on every page.—*N. Y. Journal of Medicine*, March, 1858.

We know of no treatise of the kind so complete and yet so compact.—*Chicago Med. Jour.* Jan. 1858.

A fairer, more honest, more earnest, and more reliable investigator of the many diseases of women and children is not to be found in any country.—*Southern Med. and Surg. Journal*, January 1858.

We gladly recommend his Lectures as in the highest degree instructive to all who are interested in obstetric practice.—*London Lancet*.

We have to say of it, briefly and decidedly, that it is the best work on the subject in any language; and that it stamps Dr. West as the *facile princeps* of British obstetric authors.—*Edinb. Med. Journ.*

As a writer, Dr. West stands, in our opinion, second only to Watson, the "Macaulay of Medicine;" he possesses that happy faculty of clothing instruc-

tion in easy garments; combining pleasure with profit, he leads his pupils, in spite of the ancient proverb, along a royal road to learning. His work is one which will not satisfy the extreme on either side, but it is one that will please the great majority who are seeking truth, and one that will convince the student that he has committed himself to a candid, safe, and valuable guide.—*N. A. Med.-Chirurg. Review*, July, 1858.

Happy in his simplicity of manner, and moderate in his expression of opinion, the author is a sound reasoner and a good practitioner, and his book is worthy of the handsome garb in which it has appeared.—*Virginia Med. Journal*.

We must take leave of Dr. West's very useful work, with our commendation of the clearness of its style, and the industry and sobriety of judgment of which it gives evidence.—*London Med. Times*.

Sound judgment and good sense pervade every chapter of the book. From its perusal we have derived unmixed satisfaction.—*Dublin Quart. Journ.*

BY THE SAME AUTHOR. (Just Issued.)

LECTURES ON THE DISEASES OF INFANCY AND CHILDHOOD.

Third American, from the fourth enlarged and improved London edition. In one handsome octavo volume, extra cloth, of about six hundred and fifty pages. \$2 75.

The three former editions of the work now before us have placed the author in the foremost rank of those physicians who have devoted special attention to the diseases of early life. We attempt no analysis of this edition, but may refer the reader to some of the chapters to which the largest additions have been made—those on Diphtheria, Disorders of the Mind, and Idiocy, for instance—as a proof that the work is really a new edition; not a mere reprint. In its present shape it will be found of the greatest possible service in the every-day practice of nine-tenths of the profession.—*Med. Times and Gazette*, London, Dec. 10, 1859.

All things considered, this book of Dr. West is by far the best treatise in our language upon such modifications of morbid action and disease as are witnessed when we have to deal with infancy and childhood. It is true that it confines itself to such disorders as come within the province of the physician, and even with respect to these it is unequal as regards minuteness of consideration, and some

diseases it omits to notice altogether. But those who know anything of the present condition of pædiatrics will readily admit that it would be next to impossible to effect more, or effect it better, than the accoucheur of St. Bartholomew's has done in a single volume. The lecture (XVI.) upon Disorders of the Mind in children is an admirable specimen of the value of the later information conveyed in the Lectures of Dr. Charles West.—*London Lancet*, Oct. 22, 1859.

Since the appearance of the first edition, about eleven years ago, the experience of the author has doubled; so that, whereas the lectures at first were founded on six hundred observations, and one hundred and eighty dissections made among nearly fourteen thousand children, they now embody the results of nine hundred observations, and two hundred and eighty-eight post-mortem examinations made among nearly thirty thousand children, who, during the past twenty years, have been under his care.—*British Med. Journal*, Oct. 1, 1859.
